Abstract

Esta version de el manual est?? planeado para describir la versi??n ${argo.core.version} de ArgoUML.

Este material puede ser distribuido solo sujeto a los terminos y condiciones establecidos en la Open Publication License, v1.0 o posterior. Una copia de esta licencia est?? incluida en la secci??n Open Publication License. La ??ltima versi??n est?? actualmente disponible en http://www.opencontent.org/openpub/ [http://www.opencontent.org/openpub/].
1. Prefacio .................................................................................................................. xvii
1. Introducción............................................................................................................. 1
1.1. Orígenes y Visión General de ArgoUML ............................................................ 1
   1.1.1. Análisis Orientado a Objeto y Diseño ........................................................... 1
   1.1.2. El Desarrollo de ArgoUML ......................................................................... 1
   1.1.3. Encontrando Más Sobre el Proyecto ArgoUML ....................................... 2
1.2. Alcance de Este Manual de Usuario ................................................................ 2
   1.2.1. Audiencia Objetivo .................................................................................... 2
   1.2.2. Alcance ...................................................................................................... 3
1.3. Visión General del Manual de Usuario ............................................................ 3
   1.3.1. Estructura del Manual Tutorial .................................................................. 3
   1.3.2. Estructura del Manual de Referencia ...................................................... 3
   1.3.3. Retroalimentación Por el Usuario .............................................................. 4
1.4. Supuestos .......................................................................................................... 4
1. Tutorial ................................................................................................................. 5
2. Introducción (escribiéndose) ................................................................................. 6
3. OOA&D basada en UML ....................................................................................... 7
   3.1. Antecedentes para UML .............................................................................. 7
   3.2. Procesos Basados en UML para OOA&D .................................................... 7
      3.2.1. Tipos de Procesos .................................................................................. 8
      3.2.2. Un Proceso de Desarrollo para este Manual ........................................... 10
   3.3. Por qué ArgoUML es Diferente .................................................................... 11
      3.3.1. Psicología Cognitiva ............................................................................. 12
      3.3.2. Estándares Abiertos ............................................................................. 13
      3.3.3. 100% Java Puro .................................................................................. 14
      3.3.4. Código Abierto .................................................................................... 14
   3.4. Fundamentos de ArgoUML ........................................................................... 15
      3.4.1. Empezando ............................................................................................ 15
      3.4.2. El Interfaz de Usuario de ArgoUML ..................................................... 17
      3.4.3. Salida ................................................................................................. 24
      3.4.4. Trabajando Con Críticas de Diseño ....................................................... 26
   3.5. El Caso de Estudio (A escribir) ....................................................................... 28
4. Captura de Requerimientos .................................................................................. 29
   4.1. Introducción.................................................................................................... 29
   4.2. El Proceso de Captura de Requerimientos .................................................... 29
      4.2.1. Pasos del Proceso .................................................................................. 30
   4.3. Salida del Proceso de Captura de Requerimientos ......................................... 30
      4.3.1. Documento de Visión .......................................................................... 31
      4.3.2. Diagrama de Casos de Uso ................................................................. 31
      4.3.3. La Especificación de Casos de Uso ...................................................... 34
      4.3.4. Supplementary Requirement Specification ............................................ 37
   4.4. Using Use Cases in ArgoUML ...................................................................... 38
      4.4.1. Actores ................................................................................................. 38
      4.4.2. Use Cases ............................................................................................ 38
      4.4.3. Associations ...................................................................................... 40
      4.4.4. Hierarchical Use Cases ....................................................................... 41
      4.4.5. Stereotypes ....................................................................................... 42
      4.4.6. Documentation ..................................................................................... 42
      4.4.7. System Boundary Box ........................................................................ 43
   4.5. Case Study ..................................................................................................... 43
      4.5.1. Vision Document .................................................................................... 43
      4.5.2. Identifying Actors and Use Cases ......................................................... 45
      4.5.3. Associations (To be written) ................................................................. 45
      4.5.4. Advanced Diagram Features (To be written) ....................................... 45
      4.5.5. Use Case Specifications (To be written) ............................................. 45
      4.5.6. Supplementary Requirements Specification (To be written) ............. 46
5. Analysis .................................................................................................................. 47
5.1. The Analysis Process ................................................................. 47
  5.1.1. Class, Responsibilities, and Collaborators (CRC) Cards .......... 47
  5.1.2. Concept Diagram (To be written) ........................................ 48
  5.1.3. System Sequence Diagram (To be written) ......................... 48
  5.1.4. System Statechart Diagram (To be written) ....................... 48
  5.1.5. Realization Use Case Diagram (To be written) .................... 48
  5.1.6. Documents (To be written) ................................................ 48
  5.2. Class Diagrams (To be written) ............................................. 48
    5.2.1. The Class Diagram (To be written) ................................ 48
    5.2.2. Advanced Class Diagrams (To be written) ....................... 48
  5.3. Creating Class Diagrams in ArgoUML ..................................... 49
    5.3.1. Classes ............................................................................ 49
    5.3.2. Associations (To be written) .......................................... 49
    5.3.3. Class Attributes and Operations (To be written) ............... 49
    5.3.4. Advanced Class Features (To be written) ....................... 49
  5.4. Sequence Diagrams (To be written) ....................................... 50
    5.4.1. The Sequence Diagram (To be written) ........................... 50
    5.4.2. Identifying Actions (To be written) ............................... 50
    5.4.3. Advanced Sequence Diagrams (To be written) ................. 50
  5.5. Creating Sequence Diagrams in ArgoUML ............................... 50
    5.5.1. Sequence Diagrams ......................................................... 50
    5.5.2. Actions (To be written) ................................................ 50
    5.5.3. Advanced Sequence Diagrams (To be written) ................ 50
  5.6. Statechart Diagrams (To be written) ................................... 50
    5.6.1. The Statechart Diagram (To be written) ........................... 50
    5.6.2. Advanced Statechart Diagrams (To be written) ............... 50
  5.7. Creating Statechart Diagrams in ArgoUML ............................. 50
    5.7.1. Statechart Diagrams (To be written) ............................ 50
    5.7.2. States (To be written) .................................................. 50
    5.7.3. Transitions (To be written) ......................................... 51
    5.7.4. Actions (To be written) .............................................. 51
    5.7.5. Advanced Statechart Diagrams (To be written) ............... 51
  5.8. Realization Use Cases (To be written) ................................ 51
  5.9. Creating Realization Use Cases in ArgoUML (To be written) .... 51
  5.10. Case Study (To be written) ............................................. 51
    5.10.1. CRC Cards ................................................................. 51
    5.10.2. Concept Class Diagrams (To be written) ....................... 52
    5.10.3. System Sequence Diagrams (To be written) .................... 52
    5.10.4. System Statechart Diagrams (To be written) .................. 52
    5.10.5. Realization Use Cases (To be written) ......................... 52
  6. Design .................................................................................. 53
    6.1. The Design Process (To be written) ................................ 53
      6.1.1. Class, Responsibilities, and Collaborators (CRC) Cards ...... 53
      6.1.2. Package Diagram (To be written) ................................. 54
      6.1.3. Realization Class Diagrams (To be written) ................... 54
      6.1.4. Sequence Diagrams and Collaboration Diagrams (To be written) ... 54
      6.1.5. Statechart Diagrams and Activity Diagrams (To be written) .... 54
      6.1.6. Deployment Diagram (To be written) .......................... 54
      6.1.7. Documents (To be written) ....................................... 54
    6.2. Package Diagrams (To be written) ..................................... 54
      6.2.1. The Package Diagram (To be written) .......................... 54
      6.2.2. Advanced Package Diagrams (To be written) ............... 54
    6.3. Creating Package Diagrams in ArgoUML ............................ 54
      6.3.1. Packages ................................................................. 54
      6.3.2. Relationships between packages (To be written) ............ 55
      6.3.3. Advanced Package Features (To be written) ................ 55
    6.4. More on Class Diagrams (To be written) ............................ 55
      6.4.1. The Class Diagram (To be written) .............................. 55
10. The Menu bar .............................................................................................. 72
  10.1. Introduction ...................................................................................... 72
  10.2. Mouse Behavior in the Menu Bar ......................................................... 72
  10.3. The File Menu .................................................................................. 73
      10.3.1. New .................................................................................... 73
      10.3.2. Open Project...................................................................... 73
      10.3.3. Save Project ....................................................................... 74
      10.3.4. Save Project As.. .................................................................. 74
      10.3.5. Revert to Saved .................................................................... 74
      10.3.6. Import XMI... ...................................................................... 75
      10.3.7. Export XMI... ....................................................................... 75
      10.3.8. Import Sources... ................................................................... 75
      10.3.9. Page Setup... ......................................................................... 76
      10.3.10. Print... ............................................................................... 76
      10.3.11. Export Graphics... ............................................................... 77
      10.3.12. Export All Graphics... .......................................................... 77
      10.3.13. Notation .............................................................................. 78
      10.3.14. Properties ........................................................................... 78
      10.3.15. Save Configuration .............................................................. 79
      10.3.16. Most Recent Used Files ........................................................ 80
      10.3.17. Exit .................................................................................... 80
  10.4. The Edit Menu .................................................................................. 80
      10.4.1. Select .................................................................................... 80
      10.4.2. Remove From Diagram .......................................................... 81
      10.4.3. Delete From Model ................................................................. 81
      10.4.4. Configure Perspectives... ......................................................... 81
      10.4.5. Settings... .............................................................................. 81
  10.5. The View Menu .................................................................................. 85
      10.5.1. Goto Diagram... ..................................................................... 85
      10.5.2. Find... .................................................................................. 86
      10.5.3. Zoom .................................................................................... 87
      10.5.4. Adjust Grid ........................................................................... 88
      10.5.5. Adjust Grid Snap .................................................................... 88
      10.5.6. Page Breaks ........................................................................... 88
  10.6. The Create Menu ................................................................................ 88
      10.6.1. New Use Case Diagram .......................................................... 89
      10.6.2. New Class Diagram ................................................................. 89
      10.6.3. New Sequence Diagram .......................................................... 89
      10.6.4. New Collaboration Diagram ................................................... 89
      10.6.5. New Statechart Diagram ......................................................... 90

8.3. General Information About Panes ......................................................... 69
  8.3.1. Re-sizing Panes ........................................................................... 69

8.4. The status bar ........................................................................................ 70

9. The Toolbar .................................................................................................. 70
  9.1. File operations .................................................................................. 70
  9.2. Edit operations .................................................................................. 70
  9.3. View operations ................................................................................ 70
  9.4. Create operations ................................................................................ 71

10. The Menu bar .............................................................................................. 72
  10.1. Introduction ...................................................................................... 72
  10.2. Mouse Behavior in the Menu Bar ......................................................... 72
  10.3. The File Menu .................................................................................. 73
      10.3.1. New .................................................................................... 73
      10.3.2. Open Project...................................................................... 73
      10.3.3. Save Project ....................................................................... 74
      10.3.4. Save Project As.. .................................................................. 74
      10.3.5. Revert to Saved .................................................................... 74
      10.3.6. Import XMI... ...................................................................... 75
      10.3.7. Export XMI... ....................................................................... 75
      10.3.8. Import Sources... ................................................................... 75
      10.3.9. Page Setup... ......................................................................... 76
      10.3.10. Print... ............................................................................... 76
      10.3.11. Export Graphics... ............................................................... 77
      10.3.12. Export All Graphics... .......................................................... 77
      10.3.13. Notation .............................................................................. 78
      10.3.14. Properties ........................................................................... 78
      10.3.15. Save Configuration .............................................................. 79
      10.3.16. Most Recent Used Files ........................................................ 80
      10.3.17. Exit .................................................................................... 80
  10.4. The Edit Menu .................................................................................. 80
      10.4.1. Select .................................................................................... 80
      10.4.2. Remove From Diagram .......................................................... 81
      10.4.3. Delete From Model ................................................................. 81
      10.4.4. Configure Perspectives... ......................................................... 81
      10.4.5. Settings... .............................................................................. 81
  10.5. The View Menu .................................................................................. 85
      10.5.1. Goto Diagram... ..................................................................... 85
      10.5.2. Find... .................................................................................. 86
      10.5.3. Zoom .................................................................................... 87
      10.5.4. Adjust Grid ........................................................................... 88
      10.5.5. Adjust Grid Snap .................................................................... 88
      10.5.6. Page Breaks ........................................................................... 88
  10.6. The Create Menu ................................................................................ 88
      10.6.1. New Use Case Diagram .......................................................... 89
      10.6.2. New Class Diagram ................................................................. 89
      10.6.3. New Sequence Diagram .......................................................... 89
      10.6.4. New Collaboration Diagram ................................................... 89
      10.6.5. New Statechart Diagram ......................................................... 90
15.4.2. Revise Attribute Names to Avoid Conflict ........................................ 136
15.4.3. Change Names or Signatures in an Artifact ................................. 137
15.4.4. Duplicate End (Role) Names for an Association .......................... 137
15.4.5. Role name conflicts with member ............................................ 137
15.4.6. Choose a Name (Classes and Interfaces) ..................................... 137
15.4.7. Choose a Unique Name for an Artifact (Classes and Interfaces) ... 137
15.4.8. Choose a Name (Attributes) .................................................. 138
15.4.9. Choose a Name (Operations) ................................................... 138
15.4.10. Choose a Name (States) ........................................................ 138
15.4.11. Choose a Unique Name for a (State related) Artifact ................. 138
15.4.12. Revise Name to Avoid Confusion ........................................... 138
15.4.13. Choose a Legal Name .......................................................... 138
15.4.14. Change an Artifact to a Non-Reserved Word ............................ 138
15.4.15. Choose a Better Operation Name ............................................ 138
15.4.16. Choose a Better Attribute Name ............................................. 139
15.4.17. Capitalize Class Name .......................................................... 139
15.4.18. Revise Package Name .......................................................... 139

15.5. Storage .......................................................................................... 139
15.5.1. Revise Attribute Names to Avoid Conflict ................................. 139
15.5.2. Add Instance Variables to a Class ............................................. 139
15.5.3. Add a Constructor to a Class ................................................... 139
15.5.4. Reduce Attributes on a Class ................................................... 140

15.6. Planned Extensions .......................................................................... 140
15.6.1. Operations in Interfaces must be public ..................................... 140
15.6.2. Interfaces may only have operations ......................................... 140
15.6.3. Remove Reference to Specific Subclass ..................................... 141

15.7. State Machines ................................................................................ 141
15.7.1. Reduce Transitions on <state> ................................................. 141
15.7.2. Reduce States in machine <machine> ....................................... 141
15.7.3. Add Transitions to <state> ...................................................... 141
15.7.4. Add Incoming Transitions to <artifact> .................................... 141
15.7.5. Add Outgoing Transitions from <artifact> ................................. 142
15.7.6. Remove Extra Initial States ..................................................... 142
15.7.7. Place an Initial State .............................................................. 142
15.7.8. Add Trigger or Guard to Transition ......................................... 142
15.7.9. Change Join Transitions .......................................................... 142
15.7.10. Change Fork Transitions ....................................................... 142
15.7.11. Add Choice/Junction Transitions ............................................ 142
15.7.12. Add Guard to Transition ....................................................... 142
15.7.13. Clean Up Diagram ............................................................... 142
15.7.14. Make Edge More Visible ....................................................... 142
15.7.15. Composite Association End with Multiplicity > 1 ...................... 143

15.8. Design Patterns ............................................................................... 143
15.8.1. Consider using Singleton Pattern for <class> .............................. 143
15.8.2. Singleton Stereotype Violated in <class> ................................... 143
15.8.3. Nodes normally have no enclosers .......................................... 144
15.8.4. NodeInstances normally have no enclosers ............................... 144
15.8.5. Components normally are inside nodes .................................... 144
15.8.6. ComponentInstances normally are inside nodes ....................... 144
15.8.7. Classes normally are inside components ................................... 144
15.8.8. Interfaces normally are inside components ............................... 144
15.8.9. Objects normally are inside components ................................... 144
15.8.10. LinkEnds have not the same locations .................................... 144
15.8.11. Set classifier (Deployment Diagram) ....................................... 145
15.8.12. Missing return-actions .......................................................... 145
15.8.13. Missing call(send)-action ...................................................... 145
15.8.14. No Stimuli on these links ...................................................... 145
15.8.15. Set Classifier (Sequence Diagram) ......................................... 145
18. Class Diagram Artifact Reference ................................................................. 188
17. Use Case Diagram Artifact Reference ............................................................ 169
17.1. Introduction .............................................................................................. 169
17.1.1. ArgoUML Limitations Concerning Use Case Diagrams ..................... 169
17.2. Actor ........................................................................................................ 169
17.2.1. Actor Details Tabs .............................................................................. 169
17.2.2. Actor Property Toolbar ..................................................................... 170
17.2.3. Property Fields For Actor .................................................................. 171
17.3. Use Case ................................................................................................. 172
17.3.1. Use Case Details Tabs ......................................................................... 172
17.3.2. Use Case Property Toolbar ............................................................... 173
17.3.3. Property Fields For Use Case ............................................................ 174
17.4. Extension Point ...................................................................................... 175
17.4.1. Extension Point Details Tabs ............................................................ 176
17.4.2. Extension Point Property Toolbar .................................................... 176
17.4.3. Property Fields For Extension Point .................................................. 177
17.5. Association ............................................................................................ 178
17.6. Association End ...................................................................................... 178
17.7. Dependency ............................................................................................ 178
17.8. Generalization ....................................................................................... 178
17.8.1. Generalization Details Tabs ........................................................... 178
17.8.2. Generalization Property Toolbar ..................................................... 179
17.8.3. Property Fields For Generalization .................................................. 180
17.9. Extend ..................................................................................................... 181
17.9.1. Extend Details Tabs .......................................................................... 181
17.9.2. Extend Property Toolbar ................................................................. 182
17.9.3. Property Fields For Extend ............................................................... 183
17.10. Include .................................................................................................. 184
17.10.1. Include Details Tabs ......................................................................... 185
17.10.2. Include Property Toolbar ............................................................... 185
17.10.3. Property Fields For Include ............................................................ 186
18. Class Diagram Artifact Reference .................................................................. 188
18.1. Introduction ............................................................................................ 188
18.1.1. Limitations Concerning Class Diagrams in ArgoUML ....................... 188
18.2. Package ................................................................................................... 188
18.2.1. Package Details Tabs ........................................................................ 189
18.2.2. Package Property Toolbar ............................................................... 189
18.2.3. Property Fields For Package ............................................................ 190
18.3. Datatype ................................................................................................. 191
18.4. Stereotype ............................................................................................... 191
18.5. Class ....................................................................................................... 191
18.5.1. Class Details Tabs ............................................................................ 191
18.5.2. Class Property Toolbar ................................................................. 192
18.5.3. Property Fields For Class ............................................................... 193
18.6. Attribute ................................................................................................. 195
18.6.1. Attribute Details Tabs ...................................................................... 196
18.6.2. Attribute Property Toolbar ............................................................. 197
18.6.3. Property Fields For Attribute .......................................................... 197
18.7. Operation ............................................................................................... 199
18.7.1. Operation Details Tabs .................................................................... 200
18.7.2. Operation Property Toolbar ............................................................ 200
18.7.3. Property Fields For Operation .......................................................... 201
18.8. Parameter ............................................................................................... 204
18.8.1. Parameter Details Tabs ..................................................................... 204
Prefacio

El diseño de software es una tarea cognitiva difícil. Los diseñadores deben construir manualmente diseños, pero la dificultad principal es la toma de decisiones en lugar de la entrada de datos. Si los diseñadores mejoran sus capacidades de toma de decisiones, ello resultará en mejores diseños.

Las herramientas CASE actuales proporcionan automatización e interfaces gráficos de usuario que reducen el trabajo manual de construir un diseño y transformar un diseño en código. Ayudan a los diseñadores en la toma de decisiones principalmente proporcionando visualizacíon de los diagramas y comprobaciones sintácticas simples. Ademas muchas herramientas CASE proporcionan beneficios sustanciales en el área de control de versiones y mecanismos de diseño concurrente. Un área de soporte de diseño que no ha sido bien soportada es el análisis de decisiones de diseño.

Las herramientas CASE actuales son útiles en que proporcionan una GUI (Graphic User Interface; Interfaz Grafica de Usuario) que permite a los diseñadores acceder a todas las características proporcionadas por la herramienta. Y soportan el proceso de diseño de un diseño en el estilo de metodologías de diseño populares. Pero típicamente no proporcionan soporte de proceso para guiar al diseñador a través de la tarea de diseño. En su lugar, los diseñadores típicamente comienzan con una página en blanco y deben recordar cubrir todos los aspectos del diseño.

ArgoUML es un entorno de diseño orientado a dominio que proporciona soporte cognitivo de diseño orientado a objetos. ArgoUML proporciona algunas de las mismas características de automatización de una herramienta CASE comercial, pero esta enfocado en características que soportan las necesidades cognitivas de los diseñadores. Estas necesidades cognitivas están descritas por tres teorías cognitivas.

1. reflection-in-action;
2. opportunistic design; and
3. comprehension and problem solving.

ArgoUML está basado en la especificación UML 1.4. El núcleo del modelo de repositorio es una implementación de el Java Metadata Interface (JMI) que directamente soporta MOF y usa la versión legible por máquina de la especificación UML 1.4 proporcionada por OMG.

Además, es nuestra meta proporcionar soporte exhaustivo para OCL (el Object Constraint Language) y XMI (el formato XML Model Interchange).

ArgoUML fue originariamente desarrollado por un pequeño grupo de gente como un proyecto de investigación. ArgoUML tiene muchas características que lo hacen especial, pero no implementa todas las características que una herramienta CASE comercial proporciona.

Este manual es el trabajo acumulativo de muchas personas y ha estado evolucionando durante muchos años. Conectado con la publicación 0.10 de ArgoUML, Jeremy Bennett, escribió gran cantidad de nuevo material que fue añadido a las versiones anteriores por Alejandro Ramírez, Philippe Vanpeperstraete y Andreas Rueckert. Además, algunas cosas de algunos de los otros documentos como el libro de cocina de los desarrolladores por Markus Klink y Linus Tolke, la Guía Rápida por Kunle Odutola, y el FAQ (Preguntas frecuentes) por Dennis Daniels. Conectado con la publicación 0.14 se realizaron cambios por Linus Tolke, y Michiel van der Wulp. Estos cambios fueron mayoritariamente adaptar el manual a las nuevas funciones y apariencia de la versión 0.14 de ArgoUML, y la introducción del índice. Los usuarios y desarrolladores que han contribuido proporcionando ayuda valiosa, como revisiones, comentarios y observaciones mientras leen y usan este manual son demasiados para ser nombrados.

ArgoUML está disponible gratuitamente y puede ser usado en entornos comerciales. Para los términos de uso, mira el acuerdo de licencia presentado cuando descargas ArgoUML. Estamos proporcionando el código fuente de ArgoUML para que puedas revisarlo, adecuarlo a tus necesidades y mejorarlo. Pasado el tiempo, esperamos que ArgoUML evolucione en una poderosa y útil herramienta que todos puedan usar.

Este Manual de Usuario está orientado al diseñador, quien desea usar ArgoUML. El manual está escrito asumiendo familiaridad con UML, pero eventualmente puede ayudar a aquellos nuevos en UML.

El manual está escrito en DocBook/XML y está disponible como HTML y PDF.

Dinos que piensas sobre este Manual de Usuario! Tus comentarios nos ayudarán a mejorar cosas. Mira Section 1.3.3, “Retroalimentación” por el Usuario”.
Chapter 1. Introducción

1.1. Orígenes y Visión General de ArgoUML

1.1.1. Análisis Orientado a Objeto y Diseño

Durante la última década, el Análisis Orientado a Objeto y Diseño (Object Oriented Analysis and Design; OOA&D) se ha convertido en el paradigma de desarrollo de software dominante. Con ello se ha conseguido un gran avance en los procesos de pensamiento de todos los involucrados en el ciclo de vida del desarrollo de software.

El soporte de objetos en un lenguaje de programación empezó con Simula 67, pero fue la aparición en la década de 1980 de los lenguajes híbridos, como es C++, Ada y Object Pascal lo que permitió a OOA&D despegar. Estos lenguajes proporcionaban soporte para OO además de para programación procedural. La programación Orientada a Objeto se convirtió en la corriente dominante.

Un sistema OO está diseñado y implementado como una simulación del mundo real usando artefactos software. Esta premisa es tan potente como simple. Usando un acercamiento OO para diseñar un sistema puede ser diseñado y testeado (o mas correctamente simulado) sin tener que construir el sistema real primero.

Es el desarrollo durante la década de 1990 de herramientas para soportar análisis Orientado a Objeto y diseño lo que coloco este enfoque en la corriente dominante. Cuando se combina con la capacidad de diseñar sistemas a muy alto nivel, una herramienta basada en el enfoque OOA&D ha permitido la implementación de sistemas mas complejos que los posibles previamente.

El último factor que ha propulsado OOA&D ha sido su idoneidad para modelar interfaces gráficos de usuario. La popularidad de lenguajes gráficos orientados a objeto y basados en objeto como Visual Basic y Java refleja la efectividad de este enfoque.

1.1.2. El Desarrollo de ArgoUML

Durante la década de 1980 un número de metodologías de procesos OOA&D y notaciones fueron desarrolladas por diferentes equipos de investigación. Se hizo patente que había muchos temas comunes y, durante la década de 1990, un enfoque unificado para la notación OOA&D fue desarrollado bajo el auspicio del Object Management Group [http://www.omg.org]. Este estándar se hizo conocido como el Unified Modeling Language (UML), y ahora es el lenguaje estandar para comunicar conceptos OO.

ArgoUML fue concebido como un entorno y herramienta para usar en el análisis y diseño de sistemas de software orientados a objeto. En este sentido es similar a muchos de las herramientas CASE comerciales que son vendidas como herramientas para modelar sistemas software. ArgoUML tiene un número de distinciones muy importantes de muchas de esas herramientas.

1. ArgoUML se enfoca en psicología cognitiva para proporcionar nuevas características que incrementen la productividad soportando las necesidades cognitivas de diseñadores y arquitectos de software orientado a objeto.

3. ArgoUML es una aplicación Java pura 100%. Esto permite a ArgoUML funcionar en todas las plataformas para las cuales un puerto fiable de la plataforma Java 2 está disponible.

4. ArgoUML es un proyecto de código abierto. La disponibilidad del código fuente asegura que una nueva generación de diseñadores de software e investigadores tenga acceso a un entorno de trabajo.
probado desde el que pueden conducir el desarrollo y evolución de tecnologías CASE.

UML es el lenguaje de modelado OO más prevalente y java es una de las plataformas de desarrollo OO más productivas. Jason Robbins y el resto de su equipo de investigación en la universidad de California, Irvine potenciaron estos beneficios creando ArgoUML. El resultado es un entorno y una herramienta de desarrollo sólida para diseño de sistemas OO. Es más, proporciona un campo de de pruebas para la evolución del desarrollo e investigación de herramientas CASE orientadas a objeto.

Una primera publicación de ArgoUML fue disponible en 1998 y más de 100,000 descargas a mediados de 2001 demostraron el impacto que este proyecto ha provocado, siendo popular en campos educacionales y comerciales.

1.1.3. Encontrando Más Sobre el Proyecto ArgoUML

1.1.3.1. Como está desarrollado ArgoUML

Jason Elliot Robbins fundó el Proyecto Argo y proporcionó un liderazgo temprano al proyecto. Mientras Jason permanece activo en el proyecto, ¿? ha dejado el liderazgo. El proyecto continua avanzando fuertemente. Hay más de 300 miembros en la lista de correo de desarrollador (mira http://argouml.tigris.org/servlets/ProjectMailingListList), Con un par de docenas de ellos formando el núcleo del grupo de desarrollo.

La lista de correo del desarrollador es el lugar donde toda la discusión sobre las últimas tareas toma lugar, y los desarrolladores discuten las direcciones que el proyecto debería tomar. Aunque controvertida a veces, estas discusiones son mantenidas siempre correctas y amigables (sin flame-wars y esas cosas), así que los novatos (newbies) no deberían dudar y participar en ellas. Siempre tendrás una calurosa bienvenida allí.

Si quieres aprender cómo se gestiona el proyecto y cómo contribuir a él, ve a ArgoUML Web Site Developer Zone [http://argouml.tigris.org/dev.html] y busca a través de la documentación allí expuesta. El Libro de Cocina del Desarrollador (Developers’ Cookbook) fue escrito específicamente para este propósito.

1.1.3.2. Más sobre la Infraestructura

Además de la lista de correo del desarrollador, existe también una lista de correo para usuarios (mira The ArgoUML Mailing List List [http://argouml.tigris.org/servlets/ProjectMailingListList]), donde podemos discutir problemas desde la perspectiva del usuario. Los desarrolladores también leen esa lista, así que generalmente se proporciona ayuda altamente cualificada.

Más información sobre ArgoUML y otros asuntos relacionados con UML está también disponible en el ArgoUML website [http://argouml.tigris.org], mantenido por Linus Tolke.

1.2. Alcance de Este Manual de Usuario

1.2.1. Audiencia Objetivo

La publicación actual de este documento está dirigida a usuarios experimentados de UML en OOA&D (quizás con otras herramientas) que deseen cambiar a ArgoUML.
Publicaciones futuras soportarán diseñadores que conocen OOA&D, y desean adoptar la notación UML dentro de su proceso de desarrollo.

Un objetivo a largo plazo es soportar i) aquellos que están aprendiendo diseño y desean empezar con un proceso OOA&D que usa notación UML, y ii) gente interesada en diseño de código modularizado con un GUI.

1.2.2. Alcance

La intención es que este documento proporcione una guía exhaustiva, permitiendo a los diseñadores usar ArgoUML en toda su extensión. Esto es en dos partes.

- Un manual tutorial, mostrando cómo trabajar con ArgoUML
- Un manual de referencia completo, registrando todo lo que puedes hacer con ArgoUML.

La versión 0.22 de este documento lleva a cabo la segunda de ellas.

En esta guía hay algunas cosas que no encontrarás, porque están cubiertas en otro lugar.

- Descripciones de cómo ArgoUML funciona internamente.
- Como mejorar ArgoUML con nuevas características y funciones.
- Una guía de solución de problemas.
- Un índice de referencia rápida para usar ArgoUML.

1.3. Visión General del Manual de Usuario

1.3.1. Estructura del Manual Tutorial

Chapter 2, Introducción (escribiéndose) proporciona una visión general de OOA&D basada en UML, incluyendo una guía para obtener ArgoUML instalado y funcionando.

Desde Chapter 4, Captura de Requerimientos hasta Chapter 7, Code Generation, Reverse Engineering, and Round Trip Engineering se introduce en cada parte del diseño de procesos desde la captura de los requerimientos inicial hasta el desarrollo y construcción final del proyecto.

1.3.2. Estructura del Manual de Referencia

Chapter 8, Introduction es una visión general del interfaz de usuario y proporciona un resumen del soporte para los varios tipos de diagrama UML en ArgoUML. Chapter 10, The Menu bar y Chapter 11, The Explorer describen la barra de menú, y cada una de las subventanas de la interfaz de usuario, cono-
cidas como Paneles.

Chapter 15, The Critics da detalles de todas las criticas cognitivas dentro del sistema. Finalmente ArgoUML enlazar?? directamente con este manual cuando se de notificaci??n de las criticas.

Chapter 16, Top Level Artifact Reference es una visi??n general de los artefactos (p.e. las entidades UML que pueden ser colocadas en diagramas) dentro de ArgoUML. Los siguientes cap??tulos (Chapter 17, Use Case Diagram Artifact Reference hasta Chapter 24, Built In DataTypes, Classes, Interfaces and Stereotypes) describen los artefactos que pueden ser creados por medio de cada diagrama de ArgoUML, y sus propiedades, tambi?n como algunos artefactos estar??an proporcionados con el sistema.

Se proporciona un Glossary completo. Appendix A, Supplementary Material for the Case Study proporcione material para suplementar el estudio de caso usado a lo largo del documento. Appendix B, UML resources y Appendix C, UML Conforming CASE Tools identifican la informaci??n subyacente en UML y las herramientas CASE UML. Appendix F, Open Publication License es una copia de la GNU Free Documentation License.

Una ambici??n futura es proporcionar un indice exhaustivo.

### 1.3.3. Retroalimentaci??n por el Usuario

Por favor, cuentanos que piensas sobre el Manual de Usuario. Tus comentarios nos ayudar??n a hacer mejoras. Envia por e-mail tus ideas a la Lista de Correo de Usuarios de ArgoUML [mailto:users@argouml.tigris.org]. En caso de que quisieras a??adir en los capitulos sin desarrollar deberias contactar la Lista de Correo de Desarrollador de ArgoUML [mailto:dev@argouml.tigris.org] para comprobar que nadie mas esta trabajando en esa parte. Te puedes subscribir a cualquiera de las listas de correo a traves de el Sitio Web de ArgoUML [http://argouml.tigris.org].

### 1.4. Supuestos

Esta publicaci??n del manual asume que el lector esta ya muy familiarizado con UML. Esto est?? reflejado en la sobriedad en la descripci??n de los conceptos UML en el tutorial.

El caso de estudio est?? descrito, pero a??n no totalmente a traves del tutorial. Esto ser?? realizado en futuras publicaciones del manual.
Part 1. Tutorial
Chapter 2. Introducción (escribiéndose)

Este tutorial te llevará a través de un tour sobre el uso de ArgoUML para modelar un sistema.

Un proyecto de ATM (automated teller machine; cajero automático) ha sido escogido como caso de estudio para demostrar los varios aspectos de modelado que ArgoUML ofrece. En subsiguientes secciones vamos a desarrollar el ejemplo de Cajero Automático en una descripción completa en UML. El tutorial, sin embargo, solo te guiará a través de parte de ello.

En este punto deberías crear un directorio para contener tu proyecto. Nombra el directorio de manera consistente con el resto de tu sistema de archivos. Deberías nombrar los contenidos y cualquier subdriectorio de forma equivalente por razones que se harán evidentes.

El estado del modelo al final de las secciones clave estará disponible en archivos .zargo. Estos estás disponibles de forma que puedes jugar con varias alternativas y restaurar al estado apropiado del modelo en tu área de trabajo. Estos archivos .zargo serán identificados al final de las secciones cuyo trabajo representan.

El caso de estudio será un sistema de Cajero Automático. Tu compañía es FlyByNight Industries. Tú vas a jugar dos papeles. El de Gestor de Proyecto (Project Manager) y el de Analista Diseñador (Designer Analyst).

No vamos a construir ningún Cajero Automático físicamente, por supuesto.

Primero te familiarizarás con el producto y luego iremos a través de un proceso de análisis y desarrollo para un caso de prueba.

La forma en cómo tu compañía organiza su trabajo en proyectos está determinada normalmente por asuntos de políticas y demás cosas por el estilo, por tanto, fuera del ámbito de este documento. Iremos dentro de como estructuras el proyecto en sí mismo una vez que ha sido definido.
Chapter 3. OOA&D basada en UML

En este capítulo, miramos cómo UML como notación es usado dentro de OOA&D.

3.1. Antecedentes para UML

La orientación a Objeto como concepto ha existido desde la década de 1960, y como concepto de diseño desde 1972. Sin embargo fue en la década de 1980 que empezó a desarrollarse como una alternativa creíble a enfoque funcional en análisis y diseño. Podemos identificar un número de factores.

1. La aparición como corriente dominante de lenguajes de programación como SmallTalk y particularmente C++. C++ fue un lenguaje OO pragmático derivado de C, ampliamente usado por causa de su asociación con Unix.

2. El desarrollo de potentes estaciones de trabajo (workstations), y con ellas la aparición dentro de la corriente dominante de entornos de ventanas para los usuarios. Los Interfaces Graficos de Usuario (Graphical User Interfaces; GUI) tienen una estructura de objetos inherente.

3. Un número de proyectos fallidos muy publicitados, sugiriendo que el enfoque actual no era satisfactorio.

Un número de investigadores propusieron procesos OOA&D, y con ellos notaciones. Aquellas que alcanzaron cierto éxito incluyen Coad-Yourdon, Booch, Rumbaugh OMT, OOSE/Jacobson, Shlaer-Mellor, ROOM (para diseño de tiempo real) y el híbrido Jackson Structured Development.

Durante los tempranos 1990 se hizo claro que estos enfoques tenían muchas buenas ideas, a menudo muy similares. Un gran obstáculo fue la diversidad de notación, significando que los ingenieros tenían a tener familiaridad con una metodología OOA&D, en lugar de el enfoque en general.

UML fue concebido como una notación común, que sería de interés para todos los involucrados. El estándar original fue gestionado por Rational Software (www.rational.com), en el cual tres de los investigadores clave en el campo (Booch, Jacobson y Rumbaugh estuvieron involucrados). Produjeron documentos describiendo UML v0.9 y v0.91 durante 1996. El esfuerzo fu?? tomado ampliamente por la industria a través del Object Management Group (OMG), ya bien conocido por el estándar CORBA. Una primera propuesta, 1.0 fue publicada al comienzo de 1997, con una mejorada versión 1.1 aprobada ese otoño.

ArgoUML está basado en UML v1.4, la cual fue adoptada por OMG en Marzo del 2000. La versión oficial actual es UML v1.5 fechada en Marzo del 2003, para ser reemplazada pronto por una revisión mayor, UML v2.0, la cual está en sus etapas finales de estandarización y se espera completa en 2006.

3.2. Procesos Basados en UML para OOA&D

Es importante comprender que UML es una notación para OOA&D. No describe ningún proceso en particular. Cualquier proceso adoptado, llevará al sistema por un número de fases para ser construido.

1. Captura de Requerimientos. Esto es donde identificamos los requerimientos para el sistema, usando el lenguaje del dominio del problema. En otras palabras, describimos el problema en los términos del “cliente”.

En esta etapa, aunque pensando en términos de una solución, aseguramos mantener las cosas a un alto nivel, lejos de detalles concretos de una solución específica que es conocido como abstracción.

3. Diseño. Tomamos la especificación de la fase de análisis y construimos la solución con todo detalle. Nos estamos moviendo de la abstracción del problema a su realización en términos concretos.

4. Fase de Construcción. Tomamos el diseño actual y lo escribimos en un lenguaje de programación real. Esto incluye no solo la programación, sino también la prueba de que el programa cumple los requisitos (verificación), probando que el programa realmente resuelve el problema del cliente (validación) y escribiendo toda la documentación de usuario.

3.2.1. Tipos de Procesos

En esta sección miramos a los dos tipos principales de procesos en uso por la ingeniería de software. Hay otros, pero son menos ampliamente usados.

En años recientes ha habido también un movimiento para reducir el esfuerzo requerido en desarrollar software. Esto ha llevado al desarrollo de numerosos variantes ligeras de procesos (a menudo conocidas como computación agil o programación extrema) que son apropiadas para equipos muy pequeños de ingenieros.

3.2.1.1. El Proceso en Cascada

En este proceso, cada etapa del proceso-requerimientos, análisis y construcción (código y prueba) es completada antes que la siguiente comience. Esto se ilustra en Figure 3.1, “El Proceso en Cascada”.

**Figure 3.1. El Proceso en Cascada**

Este es un proceso muy satisfactorio donde los requerimientos están bien diseñados, no se espera que cambien, por ejemplo automaticar un sistema manual bien probado.

La debilidad de este enfoque se muestra problemas menos bien definidos. Invariablemente algunas de las incertidumbres en los requerimientos no serán clarificados hasta bien entrado el análisis y el diseño, o incluso en fases de codificación, requiriendo volver atrás para rehacer trabajo.

El peor aspecto de esto, es que no cuentas con código que funcione hasta cerca del final del proyecto, y muy a menudo es solo en esta etapa en la que los problemas con los requerimientos originales (por ejemplo con la interfaz de usuario) se hacen visibles.

Esto es exacerbado, por cada etapa sucesiva requiriendo más esfuerzo que la anterior, asume que los costos de descubrimiento de un problema tardan en ser enormemente caros. Esto está ilustrado por la pirámide en Figure 3.2, “Esfuerzo Involucrado en los Pasos del Proceso en Cascada”.

**Figure 3.2. Esfuerzo Involucrado en los Pasos del Proceso en Cascada**

El proceso en cascada es probablemente aún el proceso de diseño dominante. Sin embargo debido a sus limitaciones esta cada vez más siendo sustituido por procesos iterativos, particularmente por proyectos donde los requerimientos nos están bien definidos.
3.2.1.2. Procesos de Desarrollo Iterativo

En años recientes un nuevo enfoque ha sido usado, el cual anima a conseguir al menos una parte del código funcionando tan pronto como sea posible, para conseguir descubrir problemas antes en el ciclo de desarrollo.

Estos procesos usan unas series de “mini-cascadas”, definiendo unos pocos requerimientos (los más importantes) primero, llevándolos a través del análisis, diseño y construcción para obtener una versión temprana del producto, con funcionalidad limitada, relacionada con los requerimientos más importantes. La retroalimentación de este código puede ser usada para refinar los requerimientos, apuntar problemas, etc antes de hacer más trabajo.

El proceso es entonces repetido para requerimientos adicionales para construir un producto con un paso más en funcionalidad. Otra vez retroalimentación adicional puede ser aplicada a los requerimientos.

El proceso es repetido, hasta que finalmente todos los requerimientos han sido implementados y el producto esté completo. Es esta iteración lo que da a estos procesos su nombre. Figure 3.3, “Esfuerzo Involucrado en los Pasos de un Proceso Iterativo” muestra como este proceso se compara con la estructura piramidal del Proceso en Cascada.

Figure 3.3. Esfuerzo Involucrado en los Pasos de un Proceso Iterativo

El crecimiento en popularidad de los procesos iterativos está estrechamente unido al crecimiento de OOA&D. Es la encapsulación limpia de objetos lo que permite a una parte del sistema ser construida con trozos para el código restante claramente definidos.

3.2.1.2.1. El Proceso Racional Unificado

Este proceso reconoce que nuestra vista piramidal de porciones iguales de la cascada no es realista. En la práctica las iteraciones tempranas tienden a ser pesadas en los asuntos de requerimientos de cosas (necesitas definir una cantidad razonable incluso para comenzar), mientras las iteraciones posteriores tienen más esfuerzo en las áreas de diseño y construcción.

RUP reconoce que las iteraciones pueden ser agrupadas en un número de fases de acuerdo a su etapa en el proyecto global. Cada fase puede tener una o más iteraciones.

- En la fase del principio (inception phase) las iteraciones tienden a ser pesadas en asuntos de requerimientos/analisis, mientras que cualquier actividad de construcción debe estar limitada a la emulación del diseño dentro de una herramienta CASE.

- En la fase de elaboración (elaboration phase) las iteraciones tienden a ser completar la especificación de los requerimientos, y comenzar a centrarse en el análisis y el diseño, y posiblemente la construcción del primer código real.

- En la fase de construcción (construction phase) los requerimientos y análisis están mas o menos completos, y el esfuerzo de las iteraciones está mayormente en diseño y construcción.

- Finalmente, en la fase de desarrollo (deployment phase) las iteraciones están centradas sobre la actividad de la construcción, y en particular la prueba del software.
Nota

Debería estar claro que la prueba es una parte integral de todas las fases. Incluso en las fases tempranas los requerimientos y el diseño deberían ser probados, y esto es facilitado por una buena herramienta CASE.

Usaremos un proceso iterativo en este manual, que esté ligeramente basado en RUP.

### 3.2.1.2.2. Tamaño de Iteración

Una buena regla a primera vista es que una iteración debería tomar entre seis y diez semanas para proyectos comerciales típicos. Mas largo y probablemente habrás abarcado demasiados requerimientos para hacerlos de una vez. Además pierdes enfoque en tener la siguiente iteración completa. Mas corto y probablemente no has tomado en cuenta suficientes requerimientos para hacer un avance significativo. En este caso la sobrecarga adicional asociada con una iteración puede hacerse un problema.

El número total de iteraciones depende del tamaño del proyecto. Toma el tiempo estimado (trabajando fuera/adiviñando que es un tema completo en sí mismo), y divideo en trozos de 8 semanas. La experiencia parece sugerir que las iteraciones se dividirán en una proporción de alrededor de 1:2:3:3 dentro del estilo RUP de fases de inception, elaboration, construction y deployment. Un proyecto que tiene una gran imprecisión en su especificación (algunos proyectos de investigación, por ejemplo) tenderán a ser más pesados en sus fases tempranas.

Cuando se construye un producto por contrato para un cliente el punto final está bien definido. Sin embargo, cuando se desarrolla un nuevo producto para el mercado, una estrategia que puede ser usada es decidir la fecha de lanzamiento del producto, y por tanto la fecha final para completar las labores de ingeniería (algún tiempo antes). El tiempo es entonces dividido en iteraciones, y la cantidad del producto que puede ser construido en el tiempo desarrollado. El proceso iterativo es muy efectivo donde el tiempo para la comercialización está bien definido.

### 3.2.1.3. Procesos de Desarrollo Recursivo

Muy pocos sistemas software están concebidos como artefactos monolíticos. Están divididos en sub-sistemas, modulos, etc.

Los procesos de Software son iguales, con partes tempranas del proceso definiendo una estructura de alto nivel, y reaplicando el proceso para partes de la estructura en turnos para definir cada vez mayores detalles.

Por ejemplo, el diseño inicial de un sistema telefónico puede identificar objetos para i) manejar las líneas de teléfono, ii) procesar las llamadas, iii) manejar el sistema y iv) facturar al cliente. Los procesos de software pueden entonces ser reaplicados a cada uno de esos cuatro componentes para identificar su diseño.

OOA&D con sus límites claros a los objetos, soporta naturalmente este enfoque. Esta clase de OOA&D con desarrollo recursivo se abrevia a veces como OOA&D/RD.

El desarrollo Recursivo puede ser aplicado igualmente bien a procesos de cascada o iterativos. No es una alternativa a ellos.

### 3.2.2. Un Proceso de Desarrollo para este Manual

Para el propósito de este manual usaremos un proceso iterativo descendente con desarrollo recursivo, ligeramente semejante a RUP. El caso de estudio nos llevará a través de la primera iteración, aunque al final de la sección de tutorial del manual miraremos a como el proyecto se desarrollará hasta su finalización.
Dentro de la primera iteración, abordaremos cada uno de las actividades de captura de requerimientos, análisis, diseño y construcción por turno. No todas las partes del procesos están basadas en UML o ArgoUML. Miraremos a que otro material es necesario.

Dentro de este proceso tendremos una oportunidad para ver los varios diagramas UML en uso. El rango completo de diagramas UML y como están soportados está descrito en el manual de referencia (mira Section 16.6, “Diagram”).

3.2.2.1. Captura de Requerimientos

Nuestra captura de requerimientos usarán el concepto UML de Casos de Uso. Empezando con un Vision Document veremos como los Casos de Uso pueden ser desarrollados para describir todos los aspectos del comportamiento del sistema en el dominio del problema.

3.2.2.2. Análisis

Durante la etapa de análisis, introduciremos el concepto de UML de clases para permitirnos construir una visión de alto nivel de los objetos que conformaran la solución. A veces conocida como diagrama de concepto.

Introduciremos el diagrama de secuencia y diagrama de estados para capturar requerimientos por el comportamiento global del sistema.

Finalmente, tomaremos los Casos de Uso de la etapa de captura de requerimientos, y remoldearlos en el lenguaje de dominio de la solución. Esto ilustrará las ideas UML de estereotipado y realización.

3.2.2.3. Diseño

Usamos el diagrama de paquetes UML para organizar los componentes del proyecto. Luego revisaremos el diagrama de clases, diagrama de secuencia y diagrama de estados, para mostrar cómo pueden ser usados recursivamente para diseñar la solución completa.

Durante esta parte del proceso, necesitamos desarrollar nuestra arquitectura del sistema, para definir como todos los componentes ajustaran juntos y funcionaran.

Aunque no es estrictamente parte de nuestro proceso, miraremos a como el diagrama de colaboración puede ser usado como una alternativa para, o complementar el diagrama de secuencia. Similarmente miraremos al diagrama de actividades UML como una alternativa o complemento para el diagrama de estado.

Finalmente usaremos el diagrama de despliegue UML para especificar como el sistema será finalmente realizado.

3.2.2.4. Construcción

UML no está realmente afectado con la escritura de código. Sin embargo, en esta etapa mostraremos como ArgoUML puede ser usado para generar código.

También miraremos a como la Capa de Casos de Uso UML y la Especificación de Casos de Uso son herramientas invalorables para un programa de prueba.

3.3. Por que ArgoUML es Diferente

En la introducción, listamos las cuatro aspectos clave que hacen a ArgoUML diferente: i) hace uso de ideas de psicología cognitiva, ii) está basado en estándares abiertos; iii) es 100% Java puro; y iv) es un proyecto de código abierto.
3.3.1. Psicología Cognitiva

3.3.1.1. Teoría

ArgoUML es particularmente inspirado en tres teorías dentro de la psicología cognitiva: i) reflexión-en-acción, ii) diseño oportunista iii) y comprensión y resolución de problemas.

- Reflexión-en-acción

Esta teoría observa que los diseñadores de sistemas complejos no conciben un diseño totalmente formado. En su lugar, deben construir un diseño parcial, evaluarlo, reflexionar en él, y revisarlo, hasta que estén listos para extenderlo mas allá.

Como los desarrolladores trabajan directamente sobre el diseño, sus modelos mentales de la situación del problema mejoran, por lo tanto mejoran sus diseños.

- Diseño Oportunista

Una teoría dentro de la psicología cognitiva sugiere que aunque los diseñadores planean y describen su trabajo de una forma jerárquica ordenada, en realidad, escogen tareas sucesivas basadas en el criterio de costo cognitivo.

Explicado simplemente, los diseñadores no siguen incluso sus propios planes en orden, si no que escogen pasos que son mentalmente menos caros entre las alternativas.

- Comprensión y Resolución de Problemas

Una teoría de visualización de diseño dentro de la psicología cognitiva. La teoría expone que los diseñadores deben cubrir un hueco entre su modelo mental del problema o situación y el modelo formal de una solución o sistema.

Esta teoría sugiere que los programadores de beneficiarán de:

1. Representaciones múltiples como descomposición sintáctica del programa, transiciones de estado, flujo de control, y flujo de datos. Estos permiten al programador identificar mejor elementos y relaciones en el problema y solución y por lo tanto más fácilmente crear un mapeo entre sus modelos de situación y modelos del funcionamiento del sistema.

2. Aspectos familiares de un modelo de situación, que mejoran las habilidades de los diseñadores para formular soluciones.

3.3.1.2. Aplicación Práctica en ArgoUML

ArgoUML implementa estas teorías usando un número de técnicas.

1. El diseño de un interfaz de usuario que permite al usuario ver el diseño desde diferentes perspectivas diferentes, y permite al usuario alcanzar objetivos a traves de un número de rutas alternativas.

2. El uso de procesos ejecutándose en paralelo con la herramienta de diseño, evaluando el diseño actual contra modelos de cómo un diseño puede funcionar. Estos procesos son conocidos como críticos de diseño.

3. El uso de listas de tareas pendientes (to-do lists) para comunicar sugerencias desde los críticos de diseño al usuario, además de permitir al usuario registrar áreas para acciones futuras.
4. El uso de listas de validación, para guiar al usuario a través de un proceso complejo.

3.3.2. Estandares Abiertos

UML es en sí mismo un estándar abierto. ArgoUML sobre todo ha intentado usar estándares abiertos para todas sus interfaces.

La ventaja clave de la adherencia a los estándares abiertos es que ello permite un fácil interfuncionamiento entre aplicaciones, y la habilidad de moverse de una aplicación a otra como sea necesario.

3.3.2.1. XML Metadata Interchange (XMI)

XML Metadata Interchange (XMI) es el estándar para guardar los meta-datos que confeccionan un modelo UML particular. En principio esto te permitirá tomar el modelo que has creado en ArgoUML y importarlo dentro de otra herramienta.

Esto claramente tiene ventajas in permitir al UML alcanzar su meta de ser un estándar para la comunicación.

La realidad no es tan buena. Anteriormente a UML 2.0 el archivo XMI no incluye información sobre la representación gráfica de los modelos, así que el diseño del diagrama está perdido. ArgoUML rodea este problema guardando la información gráfica separada del modelo (mira Section 3.4.3.1, “Cargando y Guardando”).

3.3.2.2. Formatos Gráficos - EPS, GIF, PGML, PNG, PS, SVG

- Portable Network Graphics (PNG) [http://en.wikipedia.org/wiki/PNG] es un estándar de ISO/IEC (15948:2004) y es también una recomendación de la W3C. PNG es un formato de imagen de mapa de bits que emplea compresión sin pérdida. PNG fue creado para mejorar y sustituir el formato GIF con un formato de archivos de imagen que no requiriera de una licencia de patente para ser usado. PNG es oficialmente pronunciado "ping" pero a menudo es simplemente deletreado "PNG" probablemente para evitar confusión con la utilidad de red ping. PNG es soportado por la librería de referencia libpng, una librería independiente de la plataforma que contiene funciones C para el manejo de imágenes PNG.

- PostScript (PS) [http://en.wikipedia.org/wiki/PostScript/] es un lenguaje de descripción de página y lenguaje de programación usado principalmente en las áreas de publicación, asistida por ordenador y electrónica.

El uso de SVG en la web está en sus primeros pasos. Hay un gran problema en la inercia debida al largo tiempo de uso de formatos basados en mapas de bits y otros formatos como Macromedia Flash or Java applets, pero además el soporte por navegadores web es todavía desigual, con soporte nativo en Opera y Firefox, pero Safari y Internet Explorer necesitan un plugin. Mira PGML más arriba.

3.3.2.3. Object Constraint Language (OCL)

Object Constraint Language (OCL) [[http://en.wikipedia.org/wiki/Object_Constraint_Language] es un lenguaje declarativo para describir reglas que se aplican a modelos UML. Fue desarrollado en IBM y ahora es parte del estándar UML. Inicialmente OCL fue solo una especificación formal de una extensión de lenguaje para UML. OCL puede ahora ser usado con cualquier metamodelo compatible con Meta-Object Facility (MOF), incluyendo UML. El Object Constraint Language es un lenguaje de texto preciso que proporciona limitaciones y expresiones de acceso a objeto en cualquier modelo MOF o metamodelo que de otra forma no puede ser expresado por notación diagramática.

3.3.3. 100% Java Puro

Java fue concebido como un lenguaje interpretado. No tenía un compilador para producir código para cualquier máquina particular. Compila código para su propio sistema, la Maquina Virtual Java (Java Virtual Machine; JVM).

Escribir un interpretador para una JVM es mucho más fácil que escribir un compilador, y estas máquinas virtuales están ahora incorporadas dentro de casi todo Navegador Web. Como resultado, la mayoría de las máquinas pueden ejecutar Java, sin trabajo adicional.

(En caso de que te preguntes porque todos los lenguajes no son como este, es porque los lenguajes interpretados tienden a ser más lentos que los compilados. Sin embargo, con el alto rendimiento de los modernos PCs, la ganancia en portabilidad merece la pena para muchas aplicaciones. Más aún, las modernas caches multinivel pueden suponer que los lenguajes interpretados, que producen un código más denso, pueden realmente no ser tan lentas de todas formas.)

Mediante la elección de escribir ArgoUML en Java puro, se hace inmediatamente disponible para el mayor número de usuarios con la mínima cantidad de esfuerzo.

3.3.4. Código Abierto

ArgoUML es un proyecto de código abierto. Esto significa que cualquiera puede tener una copia gratuita del código fuente, cambiarlo, usarlo para nuevos propósitos y cosas así. La nica (gran) obligación es que te pases tu código de la misma forma a otros. La naturaleza precisa de que puedes hacer y que no puede varia de un proyecto a otro, pero el principio es el mismo.

La ventaja es que un proyecto pequeño como ArgoUML subitamente se abre a una gran cantidad de ayuda adicional de aquellos que pueden indagar en sus ideas sobre cómo el programa puede ser mejorado. En cualquier momento pueden ser 10, 15, 20 o más personas haciendo contribuciones significativas a ArgoUML. Hacer esto comercialmente costaría más de 1 millón de $ al año.

No es solo un espíritu de puro altruismo. Contribuir en un camino para aprender “con las manos en la masa” sobre software puntero. Es una forma de adquirir visibilidad (mas de 100,000 personas han descargado ArgoUML hasta la primavera de 2001). Esto es una gran cantidad de buena experiencia en suma y muchos empleadores potenciales estarán viéndote!

Y es genial para el ego!

no es un trozo de código privativo. Es el refinamiento comercial y el soporte para librarse de riesgos usando ArgoUML en un desarrollo comercial, permitiendo a los clientes tomar ventaja de la tecnología puntera de ArgoUML.

3.4. Fundamentos de ArgoUML

El objeto de esta sección es ponerte en marcha con ArgoUML. Te llevarás a través de obtener el código y conseguirlo ejecutar.

3.4.1. Empezando

3.4.1.1. Requerimientos del Sistema

Puesto que ArgoUML está escrito en Java puro 100%, debería funcionar en cualquier máquina con Java instalado. Es necesaria una versión 1.4 o posterior de Java. Puedes tenerlo disponible, pero si no, puede ser descargada gratis de www.java.com [http://www.java.com]. Ten en cuenta que solo necesitas el Java Runtime Environment (JRE), no hay necesidad de descargar el Java Development Kit (JDK) completo.

ArgoUML necesita una cantidad razonable de recursos. Un PC con 200MHz de procesador, 64Mb de RAM y 10Mb de espacio disponible en un disco duro deberían ser adecuados. Descarga el código de la sección de Descargas de sitio web del proyecto argouml.tigris.org [http://argouml.tigris.org]. Escoge la versión que se ajusta a tus necesidades como se describe en la siguiente sección.

3.4.1.2. Opciones de Descarga

Tienes tres opciones para obtener ArgoUML.

2. Descargar el código binario ejecutable. Esta es la opción correcta si pretendes usar ArgoUML regularmente y no es muy difícil.

3. Descargar el código fuente usando CVS y compilar tu propia versión. Escoge esta opción si quieres mirar el funcionamiento interno de ArgoUML, o quieres unirte como desarrollador. Esta opción requiere el JDK completo (mira Sección 3.4.1.1, “Requerimientos del Sistema”).

Las tres opciones están libremente disponibles a través del sitio web del proyecto, argouml.tigris.org [http://argouml.tigris.org].

3.4.1.3. ArgoUML Usando Java Web Start

Hay dos pasos para esto.

Java Web Start descargará ArgoUML, lo cacheará y lo iniciará por primera vez, luego en sub-

3.4.1.4. Descargando el Binario Ejecutable

Si escoges descargar el binario ejecutable, tendr??s la elecci??n de descargar la ultima versi??n estable del c??digo (la cual ser?? mas fiable, pero no tiene todas las ultimas caracteristicas), o la versi??n actual (la cual ser?? menos fiable, pero tiene mas caracteristicas). Escoge deacuerdo con tu situaci??n.

ArgoUML est?? disponible en formatos .zip o tar.gz. Escoge el primero si eres un usuario de Microsoft Windows, y el ultimo si est??s ejecutando alguna variedad de Unix. Desempaquetandolo como sigue.

- En Windows. Descomprime el archivo .zip con WinZip, o en ultimas versiones of Windows (ME, XP) copia los archivos fuera de la carpeta comprimida y ponlos en un directorio de tu elecci??n.
- En Unix. Usa GNU tar para descomprimir y desempaquetar los archivos en un directorio de tu elecci??n tar zxvf <file>.tar.gz. Si tienes una versi??n antigual de tar, la opci??n z puede no estar disponible, as?? que usa gunzip < file.tar.gz | tar xvf -.

Deber??as tener un directorio conteniendo un numero de archivos .jar y un README.txt.

3.4.1.5. Problemas Descargando

Si te quedas completamente atascado y no tienes asistencia local, intenta el sitio web, particularmente el FAQ [http://argouml.tigris.org/faqs/users.html]. Si esto a??n no resuelve el problema, intentalno en la lista de correo de usuarios de ArgoUML.

Te puedes subscribir a traves de la secci??n de listas de correo del sitio web del proyecto argouml.tigris.org [http://argouml.tigris.org], o envia un mensaje vacio a users@argouml.org con el asunto subscribe (en ingles).

Puedes entonces enviar tu problema a users@argouml.org (en ingles) and ver como otros usuarios son capaces de ayudar.

La lista de correo de usuarios es una excelente introducci??n a la actividad vital del proyecto. Si quieres estar mas involucrado hay listas de correo adicionales que cubren el desarrollo del producto y problemas en la versi??n actual y futuras.

3.4.1.6. Ejecutando ArgoUML

Como ejecutar ArgoUML depende de si usas Microsoft Windows o alguna variedad de Unix.

- En Windows. Inicia una interfaz MSDOS por ejemplo usando Inicio/Ejecutar con “command” en el texto texto de la ventana. En la ventana, coloca el en el directorio que contiene tus archivos de ArgoUML y tecla java -jar argouml.jar. Este metodo tiene la ventaja de que la informaci??n de progreso y depuraci??n es visible en la ventana DOS. De forma alternativa crea un archivo de proceso por lotes (.bat) conteniendo el comando anterior, con un acceso directo a el en el Escriptorio. El archivo bat deber??a terminar con una sentencia de "pause" en caso de que se cree informaci??n de depuraci??n durante la ejecuci??n. En algunos sistemas, simplemente haciendo doble click en el archivo argouml.jar funciona. En otros hacer esto inicia un programa de compresion de archivos. Acude a las instrucciones de tu sistema operativo o busca ayuda para determinar como configurar esto.
• En Unix. Inicia una ventana de terminal y teclea `java -jar argouml.jar`

### 3.4.1.7. Problemas Ejecutando ArgoUML

Es inusual encontrar problemas si has tenido una descarga exitosa. Si no puedes resolver el problema, prueba la lista de correo de usuario (mira Section 3.4.1.5, “Problemas Descargando”).

- JRE equivocada. El problema más común es no tener una versión de Java Runtime Environment suficientemente moderna (debe ser 1.4 o posterior).

- Lenguaje equivocado. Si el producto aparece en un idioma que no sabes o no quieres leer, vete al segundo item de menú por la izquierda en la parte superior de la pantalla. Selecciona la entrada de menú más baja en la lista desplegada. Figure 3.5, “Estableciendo Idioma en el Panel de Apariencia” muestra esto en Ruso. Luego haz click en la segunda solapa por abajo en la columna de solapas de la izquierda. Despliega la lista como se muestra en Figure 3.5, “Estableciendo Idioma en el Panel de Apariencia”, y selecciona un idioma. Puedes ver que los idiomas están listados en ellos mismos. El idioma seleccionado en la muestra es Alemán donde la palabra para “Alemán” es “Deutsch”. Tendrás que salir de ArgoUML y reiniciarlo para que los cambios hagan efecto. Usa el botón X de arriba a la derecha.

![Figure 3.4. Encontrando el Asistente de Configuración](image)

![Figure 3.5. Estableciendo Idioma en el Panel de Apariencia](image)

### 3.4.2. El Interfaz de Usuario de ArgoUML

Antes de empezar el Caso de Estudio, necesitas familiarizarte con el interfaz de usuario. Comienza leyendo la introducción a la Referencia de la Interfaz de Usuario. Mira Chapter 8, *Introduction*.

Mientras pasas a través de este tutorial se te dirá qué hacer, y cuando hacerlo pero como hacerlo a menudo será dejado a la Referencia de la Interfaz de Usuario. No es necesario en este punto leerse toda la Referencia, pero deberías echarle un vistazo hasta familiarizarte con como encontrar cosas en ella. Todo intento será hecho para dirigirte a la parte apropiada de la Referencia en donde se aplican esos puntos en el tutorial.

![Figure 3.6. Ventana inicial de ArgoUML](image)

### 3.4.2.1. El Panel Explorador

Agarra la barra divisoria vertical y muevela atrás y adelante. Agarra la barra divisoria horizontal y muevela arriba y abajo. Juega un poco por ahí con las pequeñas flechas a la izquierda o arriba de las barras divisorias. Mira Section 8.3, “General Information About Panes”.
En este momento deberías tomarte tiempo para leer Chapter 11, *The Explorer*. No hay mucho que puedas hacer en este punto con el Panel Explorador ya que no hay nada en el salvo la raíz del árbol (actualmente "untitledModel") y dos diagramas vacíos. Sin embargo, el Panel Explorador es fundamental para casi todo lo que haces y volveremos a él una y otra vez en lo sucesivo.

Hay un control de expansión y contracción delantero del símbolo del paquete para “untitledModel” en el Panel Explorador y el símbolo de paquete para “Medium” en el Panel de Tareas Pendientes. Haz click en esos controles y observa que esos paneles son tres widgets que se comportan de forma muy parecida a como se esperaría que hicieran. El control de expansión/contracción es un signo de más (+)/menos (-) o un pomo dirigido a la derecha o abajo dependiendo del look and feel que has escogido como apariencia.

En este punto deberías probar las varias opciones disponibles para un look and feel (apariencia). Usaste el editor que establece el look and feel cuando estabas seleccionando el idioma, sin embargo, solo lo viste en Ruso. Si miras la versión Española (Inglesa en la imagen) Section 10.4.5.4, “Appearance Tab” verás que la combobox de la zona mas alta es para seleccionar el look and feel. Cuando el panel se abre por primera vez la caja contiene el valor actual. Selecciona otra, sal de ArgoUML y reiniciaelo.

Selecciona alternativamente Diagrama de clase 1 y Diagrama Use Case 1 observando que el panel de detalle cambia siguiendo los objetos seleccionados en el Explorador. El panel de detalle está descrito en el Capítulo 12. No es necesario leer el capítulo 12 en este punto, pero tampoco te hará daño.

### 3.4.2.2. El Panel de Edición

**Note**

- Tarjeta de Lectura.
- Pasa a través de un par de cambios.
- Añade algunas cosas.
- Elimina algunas cosas.
- Redimensiona cosas.
- Selecciona cosas con arrastrar y soltar.
- Selecciona cosas con click y ctrl click.
- Edita nombres integrados.
- Elimina “images/tutorial/editoverview.gif” del sistema de archivos.

### 3.4.2.3. El Panel de Detalles

**Note**

- Tarjeta de Lectura.
- Item Tarjetas Pendientes. Trata las diferencias con otras etiquetas sobre localizaciones de items seleccionados. Mantiene detalles para tratarlos en el Panel de Tarjetas Pendientes.
3.4.2.4. El Panel de Tarjetas Pendientes

Note

- Tarjeta de Lectura.
- Describe prioridades.
- Resolver items.
- Relaciona a una etiqueta de Item Pendiente en el panel de detalles.
- Elimina "images/tutorial/todooverview.gif" del sistema de archivos.

3.4.2.5. La Barra de Menús y Barras de Herramientas

La barra de menús y las barras de herramientas dan acceso a todas las características principales de ArgoUML. Así, las opciones de menús, convencionales y de la barra de herramientas que no están disponibles están sombreadas y los ítems de menús que invocan un cuadro de diálogo están seguidos por una elipsis (…).

* Menú Archivo. Te permite crear un nuevo proyecto, guardar y abrir proyectos, importar fuentes desde cualquier sitio, cargar y guardar el modelo en y desde una base de datos, imprimir el modelo, guardar los gráficos del modelo, guardar la configuración del modelo y salir de ArgoUML.

* Menú Editar. Te permite seleccionar uno o más elementos UML en un diagrama, deshacer y rehacer ediciones, eliminar elementos de diagramas o el modelo completo, vaciar la papelera y cambiar la configuración del modelo.

* Menú Visualizar. Te permite cambiar entre diagramas, encontrar objetos en el modelo, hacer zoom en un diagrama, seleccionar una representación de diagrama particular (aunque en este momento solo...
hay una), seleccionar una etiqueta particular en el menú de detalles, ajustar la rejilla, ver botones en una selección y cambiar entre notación UML y Java.

- **Menú Crear Diagrama.** Te permite crear cualquiera de los siete tipos de diagrama UML (clases, casos de uso, estados, actividad, colaboración, desarrollo y secuencia) soportados por ArgoUML.

  Los diagramas de estado y actividad solo pueden ser creados cuando una clase o actor es seleccionado, incluso las entradas relevantes del menú estarán sombreadas si esto no se ha realizado.

- **Menú Colocar (Arreglo).** Te permite alinear, distribuir, reordenar y desplazar objetos en un diagrama y establecer la estrategia de distribución del diagrama.

- **Menú Generar.** Te permite generar código Java para las clases seleccionadas o para todas las clases.

- **Menú Crítica.** Te permite cambiar el estado de la función de auto-crítica entre activado y desactivado, establecer el nivel de importancia de los problemas de diseño y metas de diseño e inspeccionar las críticas disponibles.

- **Menú Herramientas.** Este menú está sombreado permanentemente a menos que halla alguna herramienta disponible en tu versión de ArgoUML.

- **Menú Ayuda.** Este menú te da acceso a detalles de aquellos que crearon el sistema, y donde se puede encontrar ayuda adicional.

- **Barra de Herramientas de Archivo.** Esta barra de herramientas contiene algunas de las herramientas del menú Archivo.

- **Barra de Herramientas de Edición.** Esta barra de herramientas contiene algunas de las herramientas de menú Edición.

- **Barra de Herramientas de Visualizar.** Esta barra de herramientas contiene algunas de las herramientas del menú Visualizar.

- **Barra de Herramientas de Crear Diagrama.** Esta barra de herramientas contiene algunas de las herramientas del menú Crear Diagrama.

### 3.4.2.6. El Ratón

El ratón y los botones del ratón (o sus equivalentes con dispositivos de entrada alternativos) son usados en una amplia variedad de formas. En esta sección miraremos a los modos comunes de uso.

ArgoUML asume el uso de un ratón con dos botones. Nos referiremos a los botones como “botón 1” y “botón 2”. El botón 1 es el botón mas a la izquierda en un ratón de diestro, y a veces llamado como el botón “selección”. El botón 2 es llamado a veces como el botón “ajuste”.

1. **Click botón 1.** Esta acción es usada generalmente para seleccionar un elemento para operaciones subsiguientes. Si el elemento es un objeto en el explorador o en el panel de edición, serán resaltados.
En el caso de la Barra de Herramientas del Panel de Edición, ese objeto es seleccionado como el siguiente para ser añadido al diagrama (pero solo uno, haz doble click para añadir múltiples objetos). Puedes añadir al diagrama moviendo el ratón al área de edición y haciendo click otra vez.

2. Doble click botón 1. Esta acción es idéntica a la de un solo click excepto, cuando es usado con la barra de herramientas del panel de edición. Bajo estas circunstancias el objeto seleccionado será añadido múltiples veces al área de dibujo, una por cada click del botón, hasta que la herramienta es seleccionada de nuevo o se escoge otra herramienta.

3. Click botón 2. Cuando se usa sobre elementos de texto en los paneles del explorador o de detalles, o objetos gráficos en el panel de edición, éste desplegará un menú dependiente del contexto. Si el elemento no ha sido seleccionado aún serán también seleccionado.

4. Movimiento botón 1. Donde el click con botón 1 ha sido usado para desplegar un menú de la barra de menú, el movimiento con botón 1 es usado para seleccionar elementos en ese menú.

El movimiento con botón 1 también tiene un efecto en el panel de edición. Sobre objetos gráficos mover: el objeto a una nueva posición. Los objetos gráficos son seleccionados muestran asas, y estos pueden ser usados para reescalarlo.

Donde el objeto es alguna forma de conector entre otros elementos, otro movimiento botón 1 que no sea en una asa causará que se cree una nueva asa, permitiendo al conector ser articulado en ese punto. Estas nuevas asas pueden ser eliminadas moviéndolas al final del conector.

5. Movimiento botón 2. Este es usado para seleccionar elementos en un menú sensible al contexto mostrado por el uso de un click del botón 2.

Hay otros comportamientos más específicos que serán encontrados bajo los casos específicos donde son usados.

### 3.4.2.7. Dibujando Diagramas

En general los diagramas son dibujados usando la barra de herramientas del panel de edición para seleccionar el objeto deseado y haciendo click en el diagrama en la posición requerida como se describe en Section 3.4.2.6, “El Ratón”. Esa sección también explica el uso del ratón para redimensionar objetos.

Los objetos que ya estén en el modelo, pero no en un diagrama, pueden ser añadidos a un diagrama seleccionando el objeto en el explorador, usando Agregar al Diagrama del menú desplegado (botón 2) sobre ese objeto, y entonces haciendo click button 1 en la posición deseada en el diagrama.

Además de objetos UML, la barra de herramientas del panel Edición proporciona para los objetos de dibujos generales (rectángulos, círculos, líneas, polígonos, curvas, texto) formas de proporcionar información suplementaria para los diagramas.

### 3.4.2.7.1. Moviendo Elementos de Diagrama

Hay muchas maneras para mover elementos de diagrama.

#### 3.4.2.7.1.1. Usando Teclas del Ratón

Selecciona los elementos que quieres mover. Presionando la tecla Ctrl mientras seleccionas puedes seleccionar muchos elementos para mover el mismo tiempo.

Ahora presiona tus teclas de flecha. Los elementos seleccionados se mueven un poco con cada tecleo.
Si además mantienes presionada la tecla Mayusculas (Shift), se moveran un poco más rápido.

3.4.2.7.1.2. Usando la Barra de Herramientas del Panel de Edición

Haz click en el botón escoba en la barra de herramientas. Mueve tu ratón al panel de diagrama, haz click derecho y manténlo. Ahora mover tu ratón alinear los elementos.

3.4.2.7.2. Colocando Elementos

El elemento de menú Colocar (Arreglo) te permite alinear, agrupar, o desplazar elementos.

3.4.2.8. Trabajando con Proyectos

3.4.2.8.1. La Ventana de Inicio

Figure 3.6, “Ventana inicial de ArgoUML” muestra la ventana principal de ArgoUML como aparece justo después de iniciar

El área de cliente de la ventana principal, debajo del menú y la barra de herramientas, está subdividida en cuatro paneles. Empezando por el panel superior más a la izquierda, y funcionando continuamente, puedes ver el Explorador, mostrando una vista de árbol de tu modelo UML, el Panel de Edición con su barra de herramientas, dos barras de desplazamiento y un área de gris de dibujo, el Panel de Detalles con la solapa de Tareas Pendientes seleccionada, y el Panel de Tareas Pendientes con una vista de árbol de los tareas pendientes,ordenadas de distintas maneras seleccionadas via la lista desplegable en lo alto del panel.

Cada vez que ArgoUML es iniciado sin un archivo de proyecto como argumento, un nuevo proyecto en blanco es creado. Este proyecto contiene un modelo llamado untitledModel. Este modelo contiene un Diagrama de Clases en blanco, llamado Diagrama de clase 1, y un Diagrama de Casos de Uso llamado diagrama use case 1.

El modelo y los dos diagramas vacíos se pueden ver en el explorador, que es la herramienta principal para navegar a través de tu modelo.

Asumamos por un momento que este el el punto donde quieres empezar a modelar un nuevo sistema de compras. Tienes que darle el nombre “purchasingmodel” a tu modelo, y quieres almacenarlo en un archivo llamado FirstProject.

3.4.2.8.2. Guardando un Proyecto - El Menú Archivo

Por ahora ArgoUML guarda diagramas usando un estándar propuesto recientemente, Precision Graphics Markup Language (PGML). Sin embargo, tiene la opción de exportar datos gráficos como SVG para aquellos que quieran hacer uso de ello. Cuando ArgoUML soporte UML 2.0, almacenarán diagramas usando el UML 2.0 Diagram Interchange format.

Primero, salva el modelo en su estado (vacío y sin nombre) actual. En la barra de menú, haz click en Archivo, luego en Guardar Proyecto como... como se muestra en Figure 3.7, “Invocando Guardar Proyecto como...”.

Figure 3.7. Invocando Guardar Proyecto como...

Por favor, date cuenta que el menú Archivo contiene las opciones usuales para crear un nuevo proyecto, para abrir un proyecto existente, para guardar un proyecto bajo un nuevo nombre, para imprimir del diagrama actualmente mostrado, para guardar el diagrama mostrado actualmente como archivo, y para salir del programa.
Algunos de estos comandos de menú pueden ser invocados presionando combinaciones, como se indica en el menú desplegable. Por ejemplo, manteniendo presionada la tecla “Ctrl”, y presionando “N”, crearás un nuevo proyecto.

En la versión actual, ArgoUML solo puede contener un proyecto activo al mismo tiempo. Además, un proyecto solo puede contener un modelo UML. Puesto que un modelo UML puede contener un número ilimitado de elementos y diagramas, esto no debería presentar ninguna limitación; sería, incluso modelando sistemas bastante grandes y complejos.

**3.4.2.8.3. El Diálogo de Elección de Archivo**

Pero volvamos a guardar nuestro proyecto. Después de hacer click en el comando de menú Guardar Proyecto como..., obtenemos el diálogo de elección de archivo para introducir el nombre del archivo que deseamos usar como se muestra en Figure 3.8, “Diálogo de Elección de Archivo”.

**Figure 3.8. Diálogo de Elección de Archivo**

Este es un FileChooser Java estándar. Vayamos sobre ello con algún detalle.

La característica principal y destacada, es la lista de carpetas con barras de desplazamiento en el centro del diálogo. Usando la barra de desplazamiento en la derecha, puedes moverte arriba y abajo en la lista de carpetas contenida dentro de la carpeta actualmente seleccionada. Si puedes desplazarte o no, depende de la cantidad de archivos y carpetas mostradas y además como están mostradas. Si todo ajusta, entonces la ventana no es desplazable como se ve en la ilustración.

Haciendo Doble Click en una de las carpetas mostradas te introduce hace navegar dentro de esa carpeta, permitiéndote navegar rápidamente entre la jerarquía de carpetas de tu disco duro.

Date cuenta que solo los nombres de carpetas, y no nombres de archivo son mostrados en el área navegable. De echo, el diálogo de elección de archivo mostrado anteriormente no dispuesto de mostrar solo archivos de proyecto ArgoUML con la extensión .zargo, como puede verse en el control de la parte baja de la ventana etiquetado como Archivos de Tipo:

Ten en cuenta también que el nombre de carpeta seleccionado actualmente es mostrado en el control desplegable de la parte alta de la ventana etiquetado como Buscar en:. Un único click en una carpeta dentro del área navegable selecciona la carpeta en la pantalla pero no selecciona la carpeta para guardar.

En la parte superior del diálogo, sobre el área navegable de elección de carpetas, hay algunas herramientas más para navegar entre carpetas.

- El control desplegable de Carpeta. Haciendo click en la flecha hacia abajo se muestra una vista en árbol de la jerarquía de la carpeta, permitiéndote navegar rápidamente en la jerarquía, y al mismo tiempo determinar rápidamente donde nos encontramos posicionados en ella.

- El icono de Subir un Nivel. Haciendo click en este icono nos desplazaremos a la carpeta padre de la carpeta actual.

- El icono de Principal. Haciendo click en este icono nos desplazaremos a nuestro directorio home.

- El icono Nueva Carpeta. Haciendo click en este icono crearemos una nueva carpeta llamada " Carpeta nueva" bajo la carpeta actual. Después de que la carpeta est est creada puedes seleccionarla y hacer click en su nombre para cambiarle el nombre a tu elección.

- El icono de Presentación de Carpetas.
De acuerdo, ahora navegamos al directorio donde queremos guardar nuestro proyecto ArgoUML, rellena el Nombre de Archivo: con un nombre apropiado, como “PrimerProyecto” y haz click en el botón Guardar.

Ahora tienes un proyecto activo llamado PrimerProyecto, conectado al archivo PrimerProyecto.zargo.

### 3.4.3. Salida

#### 3.4.3.1. Cargando y Guardando

##### 3.4.3.1.1. Guardar archivos XMI en ArgoUML

ArgoUML guarda la información de diagrama en un archivo PGML (con extensión .pgml), la información del modelo en un archivo XMI (con extensión .xmi) y la información sobre el proyecto en un archivo con extensión .argo. Mira Section 3.4.3.2.2, “Precision Graphics Markup Language (PGML)” y Section 3.4.3.3, “XMI” para ver más acerca de PGML and XMI respectivamente.

Todos estos son luego comprimidos en zip en un archivo con extensión .zargo. Puedes extraer fácilmente el archivo .xmi del archivo .zargo usando cualquier aplicación de archivos comprimidos.

**Warning**

Seguramente hacer doble click lanzara una utilidad ZIP, si una está instalada, y NO Argo.

#### 3.4.3.2. Gráficos e Impresión

##### 3.4.3.2.1. El Graph Editing Framework (GEF)

GEF es el paquete de software que es el fundamento de los diagramas que aparecen en el Panel de Edición. GEF fue una parte integral de ArgoUML pero ha sido separada. Al igual que ArgoUML es un proyecto de código abierto disponible via Tigris [http://www.tigris.org].

##### 3.4.3.2.2. Precision Graphics Markup Language (PGML)

PGML es el formato de almacenamiento actual para la información de diagrama usado en ArgoUML. En el futuro, PGML será sustituido por el formato UML 2.0 Diagram Interchange.

##### 3.4.3.2.3. Aplicaciones Que Abren PGML

PGML is a predecessor of SVG (mira Section 3.4.3.2.5, “Scalable Vector Graphics (SVG)”). Fuera abandonado por el W3C Consortium.

Actualmente no hay otras herramientas que conozcamos trabajando en PGML.

##### 3.4.3.2.4. Imprimiendo Diagramas

Selecciona un diagrama, luego vete a Archivo>Exportar Diagramas. Puedes generar formatos GIF, PostScript, Encapsulated PostScript o SVG.

##### 3.4.3.2.5. Scalable Vector Graphics (SVG)

Un formato de gráficos vectoriales estándar del World Wide Web Consortium (W3C) ( ht-
3.4.3.2.6. Guardando Diagramas como SVG

1. Selecciona .svg como el tipo de archivo.

2. Teclea el nombre del archivo que quieras con la etiqueta .svg al final. Ejemplo midiaogramauml.svg

Et viola! SVG! Pruebalo y juega con el zoom un poco... No son perfectos, as?? que si conoces algo sobre representar bonitos SVG haznoslo saber.

La mayor??a de los navegadores modernos soportan SVG. Si el tuyo no lo hace, prueba Firefox [http://www.mozilla.com/firefox/] o consigue un plugin para tu navegador actual en adobe.com [http://www.adobe.com]

**Note**

No tendr??as barras de desplazamiento para tu SVG a menos que este embebido en HTML. ??Buena suerte y haznos saber que encuentras!

3.4.3.3. XMI

ArgoUML soporta archivos XMI 1.0, 1.1, y 1.2 que contengan modelos UML 1.3 y UML 1.4. Para una mejor compatibilidad con ArgoUML, exporta tus modelos usando UML 1.4 y XMI 1.1 o 1.2. Asegurate de desactivar cualquier extensi??n propietaria (tal como datos de diagrama de Poseidon).

Con versiones UML anteriores a UML 2.0, no es posible salvar informaci??n de diagrama, asi que no ser??n transferidos diagramas.

3.4.3.3.1. Usando XMI de Rational Rose

...

3.4.3.3.2. Usando Models Creados por Poseidon

En el di??logo Exportar proyecto a XMI, asegurate de dejar en blanco la selecci??n de Guardar con datos de diagrama.

3.4.3.3.3. Usando Modelos Creados por MagicDraw

...

3.4.3.3.4. XMI Compatibilidad con otras versiones de ArgoUML

Las versiones de ArgoUML anteriores a 0.19.7 soportaban UML 1.3/XMI 1.0. Despues de este tiempo, el formato de almacenamiento es UML 1.4/XMI 1.2 el cual no es compatible hacia atras. Posterioreles versiones de ArgoUML leer??n proyectos escritos con versiones antiguas, pero no vice versa. Si puedes
necesitar volver a una versión antigua de ArgoUML deberías ser cuidadoso de guardar una copia de seguridad de tus viejos proyectos.

Adicionalmente, si escribes archivos XMI que necesitan ser leídos por otras herramientas, deberías tomar en cuenta las diferentes versiones. Las herramientas de modelado UML más modernas deberían leer 1.4, pero puedes tener generadores de código integrados o otras herramientas que están atadas a UML 1.3.

3.4.3.5. Importando Otros Formatos XMI dentro de ArgoUML

La compatibilidad XMI entre herramientas de modelado UML ha mejorado con los años, pero puedes tener algunos problemas ocasionalmente.

ArgoUML no leer archivos XMI files que contengan modelos UML 1.5 o UML 2.0, pero deberías ser capaz de abrir la mayor parte de los archivos UML 1.4 y UML 1.3. Si encuentras uno que no puede abrir, por favor informa el bug para que un desarrollador pueda investigar.

3.4.3.6. Generando Formato XMI

Selecciona el comando Exportar Archivo como XMI y escoge un nombre de archivo.

3.4.3.4. Generación de Código

3.4.3.4.1. Código Generado por ArgoUML

Es posible compilar tu código generado con ArgoUML, si bien a menudo necesitas implementar los cuerpos de métodos, para obtener resultados utiles.

3.4.3.4.2. Generando Código para Métodos

Hasta el momento no puedes escribir código para métodos (operaciones) dentro de ArgoUML. El panel de fuentes es editable, pero los cambios son ignorados. ArgoUML es una herramienta de diseño puro por ahora, no hay funcionalidad IDE pero el deseo está ahí. Puedes considerar usar Forte y ArgoUML juntos es un buen rodeo del problema!

Puedes ayudarnos aquí si quisieras!

3.4.4. Trabajando Con Críticas de Diseño

3.4.4.1. Los Mensajes del Panel de Tarillas Pendientes de las Críticas de Diseño

Donde estamos ahora? Un nuevo proyecto ha sido creado, y está conectado al archivo PrimerProyecto.argo. Figure 3.9, “Ventana de ArgoUML Habiendo Guardado PrimerProyecto.zargo” muestra como tu ventana de ArgoUML deberá aparecer en esta etapa.

Figure 3.9. Ventana de ArgoUML Habiendo Guardado PrimerProyecto.zargo

El proyecto contiene un paquete de alto nivel llamado untitledModel, el cual contiene un diagrama de clases y un diagrama de casos de uso.

Si miramos cuidadosamente a la pantalla, podemos ver que la carpeta “Medium” en el panel de Tarillas
Pendientes (el panel de abajo a la izquierda) debe contener algunos elementos, ya que su icono de activación está representado.

Hacer click en este ícono abrirá la carpeta “Medium”. Una carpeta abierta es indicada por el ícono .

Pero que es este Panel de “Tar?nas Pendientes” de todas formas. No has grabado nada aún que ha de ser hecho, así que donde se originan esos elementos.

La respuesta es simple, y es al mismo tiempo uno de los puntos fuertes de ArgoUML. Mientras estas trabajando en tu modelo UML, tu trabajo es monitorizado continuamente y de forma invisible por un trozo de código llamado una crítica de diseño. Esto es como un mentor personal que vigila por encima de tu hombro y te notifica cada vez que ve algo cuestionable en tu diseño.

Las críticas son bastante poco entrometidas. Te dan una advertencia amigable, pero no te fuerzan dentro de principios de diseño que no quieres o no te gusta seguir. Tomemos un vistazo de que nos están diciendo las críticas. Haz click en el ícono cerca de la carpeta Medium, y haz click en el elemento Revisa el nombre del paquete UntitledModel.

Figure 3.10, “Ventana ArgoUML Mostrando el Elemento de Crítica Revisa el Nombre del paquete UntitledModel” muestra como debería verse tu pantalla ahora.

Figure 3.10. Ventana ArgoUML Mostrando el Elemento de Crítica Revisa el Nombre del paquete UntitledModel

Observa que tu selección está destacada en rojo en el Panel de Tar?nas Pendientes, y que una explicación completa aparece ahora en el Panel de Detalles (el panel de abajo a la derecha). Puedes tener que redimensionar tu Panel de Detalles o desplazarlo hacia abajo para ver el mensaje completo como se muestra en nuestro ejemplo.

Lo que ArgoUML está intentando decirte es que normalmente, los nombres de paquetes están escritos en minúsculas. El paquete principal por defecto creado por ArgoUML se llama untitledModel y por tanto viola un principio de diseño. (Realmente, este podría ser considerado como un bug dentro de ArgoUML, pero es adecuado para demostrar el funcionamiento de las críticas).

En este punto, puedes escoger cambiar el nombre del paquete manualmente, para imponer silencio en la crítica de diseño o por algún tiempo o permanentemente, o para requerir una explicación más extensa por e-mail de un experto.

No haremos nada de esto (volveremos a ello cuando hablemos sobre las críticas de diseño con más detalle) pero usaremos otra práctica característica de ArgoUML: una característica de autocorrección.

Para hacerlo, solo haz click en el botón Siguiente (Pr?ximo) del Panel de Detalles. Esto causará que un asistente de renombrar sea mostrado dentro del panel de propiedades, proponiendo usar el nombre untitledmodel (todo en minúsculas).

3.4.4.2. Críticas de Diseño Funcionando: El Asistente de Renombrar Paquete

Sustituye el nombre untitledmodel con purchasingmodel, y haz click el el botón Terminar. Figure 3.11, “Ventana de ArgoUML Mostrando el Asistente de Crítica para Renombrar el Paquete” muestra como la ventana de ArgoUML aparecerá ahora.
Figure 3.11. Ventana de ArgoUML Mostrando el Asistente de Crítica para Renombrar el Paquete

Observa ahora como la nota de la crítica de diseño en el panel de Tareas Pendientes desaparece, dejando solo la nota Añade elementos al paquete purchasingmodel en la lista de Tareas Pendientes.

Si esto no ocurre al momento, espera algunos segundos. ArgoUML hace uso intensivo de muchos hilos de ejecución que se ejecutan en paralelo. Esto puede causar demoras de algunos segundos antes de que la información se actualice en la pantalla.

El cambio del nombre del paquete deberá ser reflejado en el explorador, en la esquina superior izquierda de tu ventana de ArgoUML.

Ahora estamos preparados para crear nuestro primer diagrama UML, un diagrama de Casos de Uso, pero primero guardemos lo que hemos hecho hasta ahora.

Haz click en el elemento de menú Archivo, y selecciona Guardar Proyecto. Ahora puedes salir de forma segura de ArgoUML sin perder tu trabajo hasta el momento, o seguir creando tu primer diagrama.

3.5. El Casos de Estudio (A escribir)

*A escribir...*
Chapter 4. Captura de Requerimientos

4.1. Introducción

La captura de requerimientos es el proceso de identificar que quiere el “cliente” del sistema propuesto.

La clave en esta etapa es que estamos en el dominio de problema. En esta etapa debemos describir todo desde la perspectiva del “cliente” y en el lenguaje del “customer”.

El mayor riesgo que tenemos en la captura de requerimientos es empezar pensando en términos de posibles soluciones. Eso debe esperar hasta la Fase de Análisis (mira Chapter 5, Analysis). Uno de los pasos de la Fase de Análisis será tomar los resultados de la Fase de Requerimientos y refundirlos en el lenguaje de la solución estimada.

Recuerda que estamos usando un proceso incremental y iterativo.

Podemos tranquilamente volver atrás otra vez al proceso de requerimientos mientras desmontamos el problema en trozos más pequeños, cada uno de los cuales debe tener sus requerimientos capturados.

Ciertamente volveremos atrás a través de la fase de requerimientos en cada iteración mientras buscamos definir los requerimientos del sistema más y más.

Note

La única parte de la notación de los requerimientos especificada por el estándar UML es el diagrama de casos de uso. El resto es específico del proceso. El proceso descrito en este capítulo está muy inspirado en el Rational Unified Process.

4.2. El Proceso de Captura de Requerimientos

Empezamos con una visión general del problema que estamos resolviendo y las áreas clave de funcionalidad que debemos tratar en cualquier solución. Este es nuestro documento de visión, y debería ser de solo algunas páginas de longitud.

Por ejemplo la visión general de un cajero automático (automated teller machine; ATM) puede ser que debe soportar lo siguiente.

1. Depósitos monetarios, reembolsos monetarios y consultas de cuenta por los clientes.
2. Mantenimiento del equipamiento por los ingenieros del banco, y descarga de depósitos y carga de dinero por la sucursal local del banco.
3. Auditorias de todas las actividades enviadas al sistema central del banco.

Desde esta visión general podemos extraer las actividades principales del sistema, y los agentes externos (personas, equipamiento) que están involucrados en estas actividades. Estas actividades son conocidas como casos de uso y los agentes externos son conocidos como actores.

Los actores pueden ser personas o maquinas. Desde un punto de vista practico es beneficioso conocer la parte implicada detrás de cada maquina, puesto que solo ellos serán capaces de tratar con el proceso de captura de requerimientos.
Los casos de uso deberían ser actividades significativas para el sistema. Por ejemplo el uso por el cliente del Cajero Automático es un caso de uso. Introducir un numero PIN no lo es.

Hay una zona intermedia entre estos dos extremos. Como veremos a menudo es útil dividir casos de uso muy grandes en pequeños subcasos de uso. Por ejemplo podemos tener subcasos de uso cubriendo depósitos de dinero, retiradas de dinero y consultas de cuenta.

No hay una regla clara y rápida. Algunos arquitectos preferirían un pequeño número de casos de uso relativamente grandes, otros en cambio preferirían un número de pequeños casos de uso. Una regla útil a primera vista es que cualquier proyecto practico debería requerir no más de alrededor de 30 casos de uso (si necesita más, debería ser dividido en proyectos separados).

Luego mostramos la relación entre casos de uso y actores en uno o más diagramas de casos de uso. Para un proyecto grande puede ser necesario más de un diagrama. Normalmente los grupos de casos de uso relacionados son mostrados en un mismo diagrama.

Debemos luego dar una especificación para cada caso de uso, cubriendo su comportamiento normal, comportamientos alternativos y cualquier precondición y postcondición. Esto se refleja en un documento conocido como especificación de caso de uso.

Finalmente, puesto que los casos de uso son funcionales en su naturaleza, necesitamos un documento para capturar los requerimientos no funcionales (capacidad, rendimiento, necesidades de entorno, etc). Estos requerimientos son capturados en un documento conocido como una especificación suplementaria de requerimientos.

### 4.2.1. Pasos del Proceso

Los pasos en el proceso de captura de requerimientos pueden ser resumidos como sigue.

1. Captura una vista general del problema, y las características deseadas de su solución en el documento de visión.

2. Identificar los casos de uso y actores desde el documento de visión y mostrar sus relaciones en uno o más diagramas de casos de uso.

3. Da especificaciones de casos de uso detalladas para cada caso de uso, cubriendo el comportamiento normal y alternativo, precondiciones y postcondiciones.

4. Captura todos los requerimientos no funcionales en una especificación de requerimientos suplementarios.

En cualquier proceso de desarrollo iterativo, priorizaremos, y las iteraciones tempranas se enfocaran en capturar el comportamiento clave del los casos de uso más importantes.

La mayor parte de los procesos de captura de requerimientos modernos están de acuerdo con que es esencial que un representante autorizado del cliente esté completamente involucrado a través del proceso.

### 4.3. Salida del Proceso de Captura de Requerimientos
Casi todo el resultado del proceso de captura de requerimientos es documental. El único diagrama es el diagrama de casos de uso, mostrando las relaciones entre casos de uso y actores.

4.3.1. Documento de Visión

Las secciones típicas de este documento serán como sigue.

- **Resumen.** Una declaración del contexto, problema y objetivo de la solución.
- **Objetivos.** Que estamos intentando alcanzar (y cómo deseamos alcanzarlo).
- **Contexto de Mercado o Convenios Contractuales.** Para un desarrollo guiado por el mercado, esto debería indicar mercados objetivo, diferenciantes competitivos, eventos motivadores y cosas así. Para un desarrollo contractual esto debería explicar los factores clave contractuales.
- **Partes Implicadas.** Los usuarios (en el sentido más amplio) del sistema. Muchos de ellos se mapearán en actores, o equipamiento de control que se mapea en actores.
- **Características clave.** Los aspectos funcionales clave de la solución deseada al problema al nivel más alto. Estos se mapearán ampliamente en los casos de uso. Es de ayuda poner algo de priorización aquí.
- **Limitaciones.** Una visión general de los parámetros no funcionales del sistema. Estos serán tratados detalle en la especificación de requerimientos suplementarios.
- **Apendice.** Un listado de los actores y casos de uso que serán necesarios para cumplir esta visión. Es útil enlazar a estos desde las secciones tempranas para asegurar una cobertura exhaustiva.

4.3.2. Diagrama de Casos de Uso

Figure 4.1, “Diagrama de casos de uso básico para un sistema de Cajero Automático” muestra como esto puede ser visualizado en un diagrama de casos de uso. Los casos de uso son mostrados como ovalos, los actores como monigotes (incluso cuando son máquinas), con líneas (conocidas como asociaciones) conectando los casos de uso a los actores que estén involucrados en ellos. Un cuadro alrededor de los casos de uso enfatiza la frontera entre el sistema (definido por los casos de uso) y los actores que son externos.

**Note**

No todos los análisis gustan de usar un cuadro alrededor de los casos de uso. Es un asunto de opinión personal.

Figure 4.1. Diagrama de casos de uso básico para un sistema de Cajero Automático
Las siguientes secciones muestran cómo el diagrama de casos de uso básico puede ser extendido para mostrar información adicional sobre el sistema que está siendo diseñado.

### 4.3.2.1. Actores Activos y Pasivos

Los actores *Activos* inician la interacción con el sistema. Esto puede ser mostrado colocando una flecha en la asociación desde el actor apuntando hacia el caso de uso. En el ejemplo del Cajero Automático, el cliente es un actor activo.

La interacción con los actores *pasivos* es iniciada por el sistema. Esto puede ser mostrado colocando una flecha en la asociación desde el caso de uso apuntando hacia el actor. En el ejemplo del Cajero Automático el sistema central es un actor pasivo.

Este es un buen ejemplo donde la flecha ayuda, puesto que nos permite distinguir un sistema conducido por eventos (el Cajero Automático inicia la interacción con el sistema central) de un sistema de consulta continua (el sistema central interroga al Cajero Automático de tiempo en tiempo).

Donde un actor puede ser, una de dos, activo o pasivo, dependiendo de las circunstancias, la flecha puede ser omitida. En el ejemplo del Cajero Automático el ingeniero del banco se ajusta a esta categoría. Normalmente el está activo, poniéndose en funcionamiento en ciclos regulares para dar servicio al Cajero. Sin embargo, si el Cajero Automático detecta un fallo, puede convocar al ingeniero para repararlo.

El uso de flechas en asociaciones es referido como la *navegación* de la asociación. Veremos esto usado en otro lugar en UML más tarde.

**Figure 4.2.** Diagrama de casos de uso para un Cajero Automático mostrando navegación.

---

### 4.3.2.2. Multiplicidad

Puede ser útil mostrar la *multiplicidad* de asociaciones entre actores y casos de uso. Con esto queremos decir cuantas instancias de un actor interaccionan con cuantas instancias del caso de uso.

Por defecto asumimos que una instancia de un actor interacciona con una instancia de un caso de uso. En otros casos podemos etiquetar la multiplicidad de un extremo de la asociación con un número para indicar cuantas instancias están involucradas, o con un rango separado por dos puntos (..). Un asterisco (*) es usado para indicar un número arbitrario.

En el ejemplo del Cajero Automático, solo hay un sistema central, pero el puede estar gestionando cualquier número de Cajeros Automáticos. Así en el extremo del actor de la asociación Mantenimiento Cajero Automático, colocamos la etiqueta 1..3. Ellos pueden estar tratando con cualquier número de Cajeros Automáticos, as?? en el otro extremo colocamos la etiqueta 0..*.

Un banco local tendrá hasta tres oficiales autorizados para cargar y descargar los Cajeros Automáticos. Así en el extremo del actor de la relación Cajero Automático, colocamos la etiqueta 1..3. Ellos pueden estar tratando con cualquier número de Cajeros Automáticos, as?? en el otro extremo colocamos la etiqueta 0..*.

Puede haber cualquier número de clientes y puede haber cualquier número de sistemas de Cajero Automático que pueden usar. As?? a cada extremo de la asociación colocamos la etiqueta 0..*.

**Figure 4.3.** Diagrama de casos de uso para un sistema de Cajero Automático mostrando multiplicidad.
La multiplicidad puede abarrotar un diagrama, y a menudo no se muestra, excepto donde es crítico comprenderlo. En el ejemplo de Cajero Automático solo elegiríamos mostrar 1..3 contra el oficial del banco, ya que todos los demás son obvios por el contexto.

### 4.3.2.3. Jerarquías de Casos de Uso

En nuestro ejemplo de Cajero Automático hasta ahora tenemos solo tres casos de uso para describir el comportamiento del sistema. Mientras los casos de uso siempre deben describir un trozo significativo del comportamiento del sistema, si son demasiado generales pueden ser difíciles de describir.

Podríamos por ejemplo definir el comportamiento del caso de uso “Uso Cajero” en términos del comportamiento de los tres casos de uso más simples, “Depositar Dinero”, “Retirar Dinero” y “Consultas de Cuenta”. El caso de uso principal podría ser especificado incluyendo el comportamiento de los casos de uso subsidiarios necesarios.

Similarmente el caso de uso “Mantener Cajero” podría ser definido en términos de dos casos de uso “Mantener Equipamiento” y “Recargar Cajero”. En este caso los dos actores involucrados en el caso de uso principal es realmente solo involucrados en uno u otro de los dos casos de uso subsidiarios y esto puede ser mostrado en el diagrama.

La descomposición de un caso de uso en subcasos de uso más simples es mostrada en UML usando una relación de inclusión, una flecha punteada desde el caso de uso principal hasta el subsidiario, con la etiqueta `include`.

![Diagrama de caso de uso para un sistema de Cajero Automático mostrando relaciones de inclusión.](image)

Las relaciones de inclusión son buenas para desmantelar los comportamientos de casos de uso en jerarquías. Sin embargo podemos también querer mostrar un caso de uso que es una extensión de un caso de uso existente para atender a una circunstancia particular.

En el ejemplo del Cajero tenemos un caso de uso cubriendo la rutina de mantenimiento del Cajero, “Mantener Equipamiento”. También queremos cubrir el caso especial de una reparación no programada causada por la detección de un fallo interno por parte del Cajero.

Esto está mostrado en UML por la relación de extensión. En el caso de uso principal, especificamos un nombre para un lugar en la descripción, donde una extensión del comportamiento podría ser adjuntada. El nombre y lugar son mostrados en un compartimento separado dentro del ovalo del caso de uso. La representación de la relación de extensión es la misma que la de la relación de inclusión, pero con la etiqueta `extend`. Paralelamente a la relación de extensión, especificamos la condición bajo la cual ese comportamiento ser adjuntado.

![Diagrama de casos de uso para un sistema de Cajero Automático mostrando una relación de extensión.](image)

Las relaciones de extensión pueden ayudar a desmantelar los comportamientos de casos de uso en jerarquías. Sin embargo, podemos también querer mostrar un caso de uso que es una extensión de un caso de uso existente para atender a una circunstancia particular.

En el ejemplo del Cajero tenemos un caso de uso cubriendo la rutina de mantenimiento del Cajero, “Mantener Equipamiento”. También queremos cubrir el caso especial de una reparación no programada causada por la detección de un fallo interno por parte del Cajero.

Esto está mostrado en UML por la relación de extensión. En el caso de uso principal, especificamos un nombre para un lugar en la descripción, donde una extensión del comportamiento podría ser adjuntada. El nombre y lugar son mostrados en un compartimento separado dentro del ovalo del caso de uso. La representación de la relación de extensión es la misma que la de la relación de inclusión, pero con la etiqueta `extend`. Paralelamente a la relación de extensión, especificamos la condición bajo la cual ese comportamiento ser adjuntado.

![Diagrama de casos de uso para un sistema de Cajero Automático mostrando una relación de extensión.](image)

Las relaciones de extensión pueden ayudar a desmantelar los comportamientos de casos de uso en jerarquías. Sin embargo, podemos también querer mostrar un caso de uso que es una extensión de un caso de uso existente para atender a una circunstancia particular.

En el ejemplo del Cajero tenemos un caso de uso cubriendo la rutina de mantenimiento del Cajero, “Mantener Equipamiento”. También queremos cubrir el caso especial de una reparación no programada causada por la detección de un fallo interno por parte del Cajero.

Esto está mostrado en UML por la relación de extensión. En el caso de uso principal, especificamos un nombre para un lugar en la descripción, donde una extensión del comportamiento podría ser adjuntada. El nombre y lugar son mostrados en un compartimento separado dentro del ovalo del caso de uso. La representación de la relación de extensión es la misma que la de la relación de inclusión, pero con la etiqueta `extend`. Paralelamente a la relación de extensión, especificamos la condición bajo la cual ese comportamiento ser adjuntado.

![Diagrama de casos de uso para un sistema de Cajero Automático mostrando una relación de extensión.](image)

Las relaciones de extensión pueden ayudar a desmantelar los comportamientos de casos de uso en jerarquías. Sin embargo, podemos también querer mostrar un caso de uso que es una extensión de un caso de uso existente para atender a una circunstancia particular.

En el ejemplo del Cajero tenemos un caso de uso cubriendo la rutina de mantenimiento del Cajero, “Mantener Equipamiento”. También queremos cubrir el caso especial de una reparación no programada causada por la detección de un fallo interno por parte del Cajero.

Esto está mostrado en UML por la relación de extensión. En el caso de uso principal, especificamos un nombre para un lugar en la descripción, donde una extensión del comportamiento podría ser adjuntada. El nombre y lugar son mostrados en un compartimento separado dentro del ovalo del caso de uso. La representación de la relación de extensión es la misma que la de la relación de inclusión, pero con la etiqueta `extend`. Paralelamente a la relación de extensión, especificamos la condición bajo la cual ese comportamiento ser adjuntado.
El caso de uso “Mantener Equipamiento” define un nombre “Unsched”, al comienzo de su descripción. El caso de uso extendido “Unscheduled Repair” es adjuntado cuando el Cajero detecta un error interno.

Figure 4.5. Diagrama de casos de uso para un sistema de Cajero Automático mostrando una relación de extensión.

Los casos de uso pueden ser enlazados juntos de una forma adicional. Un caso de uso puede ser una generalización de un caso de uso subsidiario (o alternativamente el subsidiario es una especialización del caso de uso principal).

Esto es muy parecido a la relación de extension, pero sin la limitación de puntos de extensión específicos en los cuales el caso de uso principal puede ser extendido, y sin condiciones sobre cuando puede ser usado el caso de uso subsidiario.

La generalización es representada en un diagrama de casos de uso por una flecha con una línea continua y una punta de flecha blanca desde el subsidiario al caso de uso principal.

Esto puede ser útil cuando un caso de uso subsidiario especializa el comportamiento del caso de uso principal en un gran número de posiciones y bajo un amplio rango de circunstancias.

Sin embargo la falta de alguna restricción hace la generalización muy difícil de especificar con precisión. En general usa una relación de extensión en su lugar.

4.3.3. La Especificación de Casos de Uso

Cada caso de uso debe ser documentado para explicar en detalle el comportamiento que está especificando. Este documento es conocido por diferentes nombres en diferentes procesos: especificación de caso de uso, escenario de caso de uso o incluso (confusamente) solo caso de uso.

Un caso de uso típico incluiría las siguientes secciones.

- **Nombre.** El nombre del caso de uso al que esto se refiere.

- **Objetivo.** Un resumen de una o dos líneas de que realiza este caso de uso por sus actores.

- **Actores.** Los actores involucrados en este caso de uso, y cualquier contexto con respecto a su participación.

**Nota**

Esto no debería ser una descripción del actor. Eso debería estar asociado con el actor en el diagrama de casos de uso.

- **Pre-condición.** Sería mejor llamarlas “pre-asunciones”, pero el término usado en todos sitios es pre-condiciones. Es una declaración de cualesquiera asunciones de simplificación que podemos hacer al comienzo del caso de uso.

En el ejemplo del Cajero Automático, podemos hacer la asunción que un ingeniero está siempre disponible, y no necesitamos preocuparnos sobre el
caso de que una visita de mantenimiento de rutina se halla dejado pasar.

**Caution**

Evita pre-condiciones todo lo posible. Necesitas tener la absoluta certeza de que las pre-condiciones caben bajo todas las posibles circunstancias. Si no tu sistema estar?? debilmente especificado y por lo tanto fallara cuando la pre-condici??n no es cierta. Alternativamente, cuando no tienes la certeza de que la pre-condici??n es cierta, necesitas especificar un segundo caso de uso para manejar la pre-condici??n siendo falsa. En el primer caso, las pre-condiciones son una fuente de problemas, en el segundo una fuente de mas trabajo.

- **Flujo B??sico.** La secuencia lineal de pasos que describen el comportamiento de el caso de uso en el escenario “normal”. Donde un caso de uso tiene un ??mero de escenarios que podr??an ser normales, uno es seleccionado arbitrariamente. Especificar el flujo b??sico est?? descrito con mas detalle mas Section 4.3.3.1, “Especificando el Flujo Basico” abajo.

- **Flujos Alternativos.** Unas series de secuencias lineales describiendo cada uno de los comportamientos alternativos al flujo b??sico. Especificar flujos alternativos est?? descrito con mas detalle en Section 4.3.3.2, “Especificando los Flujos Alternativos”.

- **Post-condiciones.** Ser??a mejor llamarlas “post-asumciones”. Esta es una especificaci??n de cualesquiera asumciones que podemos hacer al final del caso de uso. Son mas utiles donde el caso de uso es uno de una serie de casos de uso subsidiarios que estan incluidos en un caso de uso principal, donde pueden formar las pre-condiciones del siguiente caso de uso que va a ser incluido.

  **Caution**

  Como las pre-condiciones, las post-condiciones son mejor evitarlas. Colocan una carga en la especificaci??n de los flujos de caso de uso, para asegurar que la post-condici??n siempre se mantiene. Por lo tanto son tambien una fuente de problemas y trabajo extra.

- **Requerimientos.** En un mundo ideal el documento de visi??n, los diagramas de casos de uso, las especificaciones de casos de uso y la especificacion de requerimientos suplementarios formari??n los requerimientos para un proyecto.

  Para la mayor??a de los desarrolladores del mercado, donde la propiedad de los requerimientos esta dentro del mismo negocio que el equipo que har?? el desarrollo, este no es normalmente el caso. El departamento de marketing puede aprender captura de requerimientos basada en los casos de uso y analisis para enlazar con las actividades primarias de sus consumidores.

  Sin embargo para desarrolladores externos por contrato, los consumidores pueden insistir en una “lista de caracteristicas” tradicional como la base del contrato. Cuando este es el caso, esta secci??on de la especificaci??n de casos de uso debe??n de ser cubiertas por el caso de uso.

  Esto es hecho a menudo a traves de una herramienta de terceros que puede enlazar documentos, proporcionando una prueba automatizada de cobertura de requisitos, en tal caso esta secci??n no es necesaria, o puede ser generada automaticamente.

El tamaño final de la especificaci??on de caso de uso depender?? de la complejidad del caso de uso.
Como pequeña regla, la mayoría de los casos de uso toman alrededor de 10-15 páginas para especificar, la mayoría de las cuales son flujos alternativos. Si el tuyo es mucho más largo que esto, considera simplificar el caso de uso. Si el tuyo es mucho más pequeño considera que el caso de uso está describiendo una parte demasiado pequeña del comportamiento.

4.3.3.1. Especificando el Flujo Basico

Todos los flujos en una especificación de casos de uso son lineales (esto es que no hay ramas condicionales). Cualquier elección en los flujos son manejadas especificando otro flujo alternativo que recoge el punto de elección. Es importante recordar que estamos especificando comportamiento aquí, no programando.

Un flujo es especificado como una serie de pasos numerados. Cada paso debe implicar alguna interacción con un actor, o al menos generar un cambio que sea observable externamente por un actor. La captura de requerimientos no debería estar especificando comportamiento interno y oculto del sistema.

Por ejemplo, nosotros podemos dar la siguiente secuencia de pasos para el flujo básico del caso de uso “Retirar Dinero” en nuestro ejemplo de Cajero Automático.

1. Consumidor indica que se requiere recibo.
2. Consumidor introduce cantidad de dinero requerido.
3. Cajero Automático verifica con el ordenador central que el consumidor puede realizar esta operación.
4. Cajero Automático entrega el dinero al consumidor.
5. Cajero Automático emite recibo al consumidor.

Recuerda que esta es un sub-caso de uso incluido en el caso de uso principal “Usar Cajero Automático”, el cual presumiblemente manejar la verificación de tarjetas y PINs antes de invocar este caso de uso incluido.

**Nota**

El primer paso no es una condición. Tomamos como nuestro flujo básico el caso donde el consumidor quiere un recibo. El caso donde el consumidor no quiere un recibo será un flujo alternativo.

4.3.3.2. Especificando los Flujos Alternativos

Esta captura los escenarios alternativos, como flujos lineales, mediante referencia a la flujo básico. Inicialmente únicamente construimos una lista de los flujos alternativos.

A.

A. Consumidor no requiere recibo.
   1. A. La cuenta del consumidor no soporta el retiro de dinero.
   2. A. Comunicación con el ordenador central está interrumpida.
A. El consumidor falla a coger el dinero entregado.
5.

Subsequently we flesh out each alternate flow, by reference to the basic flow. For example the first alternate flow might look like.

A.
A. Customer does not require a receipt.
1.
A. At step 1 of the basic flow the customer indicates they do not want a receipt.
1.
A. The basic flow proceeds from step 2 to step 4, and step 5 is not used.
1.
2.

The convention is to number the various alternate flows as A.1, A.2, A.3, etc. The steps within an alternate flow are then numbered from this. So the steps of the first alternate flow would be A.1.1, A.1.2, A.1.3, etc.

4.3.3.3. Iterative Development of Use Case Specifications

Iterative development will prioritize the use cases, and the first iterations will address the most important.

Early iterations will capture the basic flows of the most important use cases with only essential detail and list the headings of the main alternate flows.

Later iterations will address the remaining use cases, flesh out the steps on individual alternate flows and possibly provide more detail on individual steps.

4.3.4. Supplementary Requirement Specification

This captures the non-functional requirements or constraints placed on the system. Since use cases are inherently functional in nature, they cannot capture this sort of information.

Note

Some analysts like to place non-functional requirements in a section at the end of each use case specification, containing the non-functional requirements relevant to the use case.

I don't like this for two reasons. First key non-functional requirements (for example about performance) may need to appear in many use cases and it is bad practice to replicate information. Secondly there are invariably some non-functional requirements that are system wide and need a system wide document. Hence my preference for a single supplementary requirements specification.

There should be a section for each of the main areas of non-functional requirements. The checklist provided by Ian Sommerville in his book Software Engineering (Third Edn, Addison-Wesley, 1989) is a useful guide.

- **Speed.** Processor performance, user/event response times, screen refresh time.
- **Size.** Main memory (and possibly caches), disc capacity.
- **Ease of use.** Training time, style and detail of help system.
• **Reliability.** Mean time to failure, probability of unavailability, rate of failure, availability.

• **Robustness.** Time to restart after failure, percentage of events causing failure, probability of data corruption on failure.

• **Portability.** Percentage of target-dependent code/classes, number of target systems.

To this we should add sections on environment (temperature, humidity, lightening protection status) and standards compliance.

### 4.4. Using Use Cases in ArgoUML

ArgoUML allows you to draw use case diagrams. When you create a new project it has a use case diagram created by default, named *use case diagram 1*. Select this by button 1 click on the diagram name in the explorer (the upper left quadrant of the user screen).

New use case diagrams can be created as needed through *Create Diagram* on the main menu bar or on the Create Diagram Toolbar. They are edited in the editing pane (the upper right quadrant of the user screen).

#### 4.4.1. Actors

To add an actor to the diagram use button 1 click on the actor icon on the editing pane toolbar ( ) and then button 1 click at the location where you wish to place it. The actor can be moved subsequently by button 1 motion (i.e. button 1 down over the actor to select it, move to the new position and button 1 release to drop the actor in place.

Multiple actors can be added in one go, by using button 1 double click on the actor icon. Each subsequent button 1 click will drop an actor on the diagram. A button 1 click on the select icon ( ) will stop adding actors.

The actors name is set in its property panel. First select the actor (if not already selected) on the editing pane using button 1 click. Then click on the *Properties* tab in the details pane. The name is entered in the name field, and will appear on the screen.

As a shortcut, double button 1 click on the name of the actor in the editing pane (or just typing on the keyboard when an actor is selected) will allow the name to be edited directly. This is a convenient way to enter a name for a new actor.

Having created the actor, you will see it appear in the explorer (the upper left quadrant of the user screen). This shows all the artifacts created within the UML design. A drop down at the top of the explorer controls the ordering of artifacts in the explorer. The most useful are the *Package-centric* (default) and *Diagram-centric*. The latter shows artifacts grouped by the diagram on which they appear.

#### 4.4.2. Use Cases

The procedure for adding use cases is the same as that for adding actors, but using the use case icon on the editing pane toolbar ( ).

By default use cases in ArgoUML do not display their extension points (for use in extend relationships). You can show the extension point compartment in one of two ways.

1. Select the use case in the editing pane with button 1 click, then select the *Style* tab in the details
pane and button 1 click on the Display: Extension Points check box.

2. Use button 2 click over the use case in the editing pane to display a context-sensitive pop-up menu and from that choose Show/Show Extension Point Compartment.

The same approaches can be used to hide the extension point compartment.

### 4.4.2.1. Adding an Extension Point to a Use Case

There are two ways to add an extension point to a use case.

1. Select the use case on the editing pane with button 1 click. Then click on the Add Extension Point icon ( ) on the toolbar, and a new extension point with default name and location will be added after any existing extension points.

   **Note**

   The Add Extension Point icon is grayed out and unusable until a use case is selected.

2. Select the use case on the editing pane with button 1 click and then select its property tab in the details pane. A button 2 click over the Extension Points: field will bring up a context-sensitive pop-up menu. Select Add to add a new extension point.

   If any extension points already exist, they will be shown in this field on the property tab. The new extension point will be inserted immediately before the entry over which the pop-up menu was invoked. This ordering can be changed later by using the Move Up and Move Down entries on the pop-up menu.

Whichever method is used, the new extension point is selected, and its property tab can be displayed in the details pane. The name and location of the extension point are free text, set in the corresponding fields of the property tab.

An existing extension point can be edited from its property tab. The property tab can be reached in two ways.

1. If the extension point compartment for the use case is displayed on the diagram, select the use case with button 1 click and then select the extension point with a further button 1 click. The property tab can then be selected in the details pane.

2. Otherwise select the use case and its property tab in the details pane. A button 1 click on the desired entry in the Extension Points field will bring up the property tab for the extension point in the details pane.

The name and location fields of the extension point may then be edited.

As a shortcut, where the extension point compartment is displayed, double click on the extension point allows text to be typed in directly. This is parsed to set name and location for the extension point.

Extension points may be deleted, or their ordering changed by using the button 2 pop-up menu over the Extension Points field in the use case property tab.

Having created an extension point, it will appear in the explorer (upper left quadrant of the user screen).
Extension points are always shown in a sub-tree beneath their owning use case.

4.4.3. Associations

To join a use case to an actor on the diagram use button 1 click on the association icon on the editing pane toolbar ( ). Hold button 1 down at the use case, move to the actor and release button 1 (or alternatively start at the actor and finish at the use case).

This will create a straight line between actor and use case. You can segment the line by holding down button 1 down on the line and moving before releasing. A vertex will be added to the line, which you can move by button 1 motion. A vertex can be removed by picking it up and sliding to one end of the line.

Multiple associations can be added in one go, by using button 1 double click on the association icon. Each subsequent button 1 down/motion/release sequence will join an actor to a use case. Use button 1 on the select icon ( ) to stop adding associations.

It is also possible to add associations using small “handles” that appear to the left and right of a use case or actor when it is selected and the mouse is over it. Dragging the handle from a use case to an actor will create an association to that actor (and similarly by dragging a handle from an actor to a use case).

Dragging a handle from a use case into empty space will create a new actor to go on the other end. Similarly dragging a handle from an actor into empty space will create a new use case.

It is possible to give an association a name, describing the relationship of the actor to the use case, although this is not usually necessary. This is done through the property tab of the association. Such a name appears alongside the association near its center.

4.4.3.1. Setting Navigation

There are two ways of setting the navigation of an association.

1. Use button 2 click on the association to bring up a context-sensitive pop-up menu. The Navigability sub-menu has options for bi-directional navigation (the default, with no arrows) and for navigability Actor???Use Case and Use Case???Actor.

2. Use button 1 to select the association and select its property tab in the details pane. This shows a field named Association Ends:, with entries for each end labeled by the actor or use case name and its multiplicity. Select the end that should be at the tail of the arrow with button 1 click. This brings up the property tab for the association end. Use button 1 click to uncheck the Navigability box.

Note

This may seem counter-intuitive, but in fact associations by default are navigable in both directions (when no arrows are shown). This process is turning off navigation at one end, rather than turning it on at the other.

You will see it is possible to give an association end a name in its property tab. This name will appear at that end of the association, and can be used to indicate the role being played by an actor or use case in an association.

For example a time management system for a business may have use cases for completing time sheets and for signing off time sheets. An employee actor may be involved in both, one as an employee, but the other in a role as manager.
4.4.3.2. Setting Multiplicity

There are two ways of setting multiplicity at the end of an association.

1. Button 2 click over the end of an association will cause a context-sensitive pop-up menu to appear with a sub-menu labeled Multiplicity. This allows you to select from 1 (the default), 0..1, 0..* and 1..*.

2. Bring up the property sheet for the association end as described for setting navigation (see the second option in Section 4.4.3.1, “Setting Navigation”). A drop down menu gives a range of multiplicity options that may be selected.

The second of these two approaches has a wider range of options, although ArgoUML does not currently allow the user to set an arbitrary multiplicity.

4.4.4. Hierarchical Use Cases

4.4.4.1. Includes

The procedure for adding an include relationship is the same as that for adding an association, but using the include icon from the editing pane toolbar ( ) to join two use cases.

Since include relationships are directional the order in which the two ends are selected is important. The including (main) use case should be selected first (button 1 down) and the included (subsidiary) use case second (button 1 release).

It is possible to name include relationships using the property tab, but this is rarely done, and will not be displayed on the use case diagram.

4.4.4.2. Extends

The procedure for adding an extend relationship is the same as that for adding an include relationship, but using the extend icon from the editing pane toolbar ( ) to join two use cases.

As with include relationships, the order of selection matters. In this case, the extending (subsidiary) use case should be selected first (button 1 down) and the extending (main) use case second (button 1 release).

**Note**

This is the reverse of the include relationship, but reflects the way that designer’s tend to think. The fact that the extend icon’s arrow points upward (the opposite of the include icon) should help remind you of this.

To set a condition for the extend relationship, select the extend relationship in the editing pane (button 1 click) and then bring up its property tab in the details pane ((button 1 click on the tab). The text of the condition may be typed in the Condition field. Long conditions may be split over several lines if desired. The condition is displayed under the ??extend?? label on the diagram.

It is possible to name extend relationships using the property tab, but this is rarely done, and will not be displayed on the use case diagram.

4.4.4.3. Generalization
The procedure for adding generalizations, is the same as for adding extend relationships, but using the generalization icon from the editing pane toolbar ( ).

Since generalization is a directed relationship, the order of selection matters. The specialized use case should be selected first (button 1 down) and the generalized second (button 1 release).

It is also possible to add generalizations using small “handles” that appear to the top and bottom of a use case when it is selected. Dragging the handle at the top to another use case will create a generalization. The original use case is the specializing end, and the use case to which the handle was dragged will be the generalizing end. Dragging into empty space will create a new use case to be the generalizing end.

Similarly dragging on the bottom handle will create a generalization in which the original use case is the generalizing end.

Generalization is also permitted between actors, although its use is beyond the scope of this tutorial. Unlike use cases there are no generalization handles on actors, so generalizations must be created using the toolbar icon.

It is possible to name generalization relationships using the property tab, but this is rarely done. If a name is provided, it will be displayed on the use case diagram.

### 4.4.5. Stereotypes

UML has the concept of stereotyping as a way of extending the basic notation. It may prove useful for example to model a problem at both the business level and the engineering level. For both of these we will need use cases, but the use cases at the business level hold a different sort of information to those at the engineering level. Very likely they use different language and notation in their underlying use case specifications.

*Stereotypes* are used to label UML artifacts such as use cases, to indicate that they belong to a certain category. Such labels are shown in guillemots ( ????) above the name of the artifact on the diagram. The UML standard defines a number of standard stereotypes, and the user may define more stereotypes of his own.

You will see that ArgoUML has a drop down selector, *Stereotype* on every property tab. This is populated with the standard stereotypes, to which you may add your own user defined ones.

The details of stereotyping are beyond the scope of this tutorial. The reference manual (see Section 16.5, “Stereotype”) documents the support provided in ArgoUML.

**Warning**

ArgoUML is missing a few of the standard UML stereotypes. In addition not all artifacts will actually display the stereotype on the diagram. At present this includes use cases and actors.

### 4.4.6. Documentation

ArgoUML has some simple documentation facilities associated with artifacts on a diagram. In general these should be used only to record the location of material in documents that can be handled by a mainstream editor or word processor, not the actual documentation itself.

Documentation for a particular artifact is recorded through the documentation tab in the details pane (the quadrant of the user screen at the bottom right).

In addition annotation may be added to diagrams using the text icon on the editing pane toolbar ( ).

42
The recommendation is that a use case diagram should use the documentation tab of actors to record information about the actor, or if the actor is complex to refer to a separate document that holds information about the actor.

The documentation tab of use cases should record the location of the use case specification. The information in a use case specification (for all but the simplest use cases) is too complex to be placed directly in the tab.

The project should also have a separate vision document and supplementary requirements specification. A text annotation on diagrams may be used to refer to these if the user finds this helpful.

Warning

The documentation tab includes a Deprecated check box. The state of this flag is not preserved over save and load in the current release of ArgoUML.

4.4.7. System Boundary Box

ArgoUML provides a series of tools to provide arbitrary graphical annotation on diagrams (we have already mentioned the text tool). These are found at the right hand end of the editing pane toolbar and are fully documented in the reference manual (see Chapter 12, The Editing Pane).

The rectangle tool can be used to draw the boundary box. Use the button 2 context-sensitive Ordering pop-up menu to place it behind everything else. However there is no way to change its fill color from the default white. You may therefore prefer to draw the boundary box as four lines. This is the method used for the diagrams in this chapter.

Note

The editing pane in ArgoUML has a grid to which objects snap to aid in drawing. The size of this grid and its effect may be altered through the View menu (using Adjust Grid and Adjust Grid Snap). This is described fully in the reference manual (see Chapter 10, The Menu bar).

4.5. Case Study

4.5.1. Vision Document

A vision document contains more than those things needed for the modeling effort. It also contains financial and scheduling pertinent information. The following sections are those parts of the Vision Document spelled out in Section 4.3.1, “Documento de Visión” above. In practice this format need not be followed religiously, but is used here for consistency.

4.5.1.1. Summary

The company wishes to produce and market a line of ATM devices. The purpose of this project is to produce the hardware and the software to drive it that are both maintainable and robust.

4.5.1.2. Goals

To produce better designed products based on newer technology. Follow the MDA philosophy of the OMG by producing first a Platform Independent Model (PIM). As current modeling technology does not admit of maintaining the integrity of the connection between the PIM and Platform Specific Models.
(PSMs), the PIM will become comparatively stable before the first iteration of the PSM is produced. The software platform will be Java technology. The system will use a simple userid (from ATM card) and password (or PIN) mechanism.

4.5.1.3. Market Context

Equipment currently on the market is based on older technology for both hardware and software. This technology has not reached the end of its useful life, making it unlikely that the vendors of that gear are going to update it in the near future. On the other hand newer technology is available that would put us at a competitive advantage if implemented now.

4.5.1.4. Stakeholders

Among the stakeholders for this system are the Engineering Department, the Maintenance Department, and the Central Computer Facility. The full list of these stakeholders and the specific individuals representing them are.

- Engineering. Bunny, Bugs
- Maintenance. Hardy, Oliver
- Computer Facility. Laurel, Stanley
- Chief Executive Officer. Hun, Atilla The
- Marketing. Harry, Oil Can

4.5.1.5. Key Features

Cash deposit, cash withdrawal, and account inquiries by customers. Customers include people who have accounts at the owning bank as well as people who wish to make withdrawals from accounts in other banks or from credit card accounts.

Maintenance of the equipment by the bank’s engineers. This action may be initiated by the engineer on a routine basis. It may also be initiated by the equipment that can call the engineer when it detects an internal fault.

Unloading of deposits and loading of cash by officials of the local bank branch. These actions occur either on a scheduled basis or when the central computer determines that the cash supply is low or the deposit receptacle is liable to be getting full.

An audit trail for all activities will be maintained and sent periodically to the bank’s central computer. It will be possible for the maintenance engineer to save a copy of the audit trail to a diskette for transporting to the central computer.

Both dialup and leased line support will be provided. The ATM will continue to provide services to customers when communications with the central computer is not available.

4.5.1.6. Constraints

The project must be completed within nine months. It must cost no more than 1,750,000 USD excluding production costs. Components may be contracted out, but the basic architecture as well as the infrastructure will be designed in house. Close liaison must be maintained between the software development and the design, development and production of the hardware. Neither the hardware nor the software shall be considered the independent variable, but rather they shall be considered equal.
4.5.1.7. Appendix

The following are the actors that directly support this vision. Additional actors may be identified later that are needed to support this or that technology. They should not be added to this list unless they are deemed to directly support the vision as described in this document.

• Central Computer
• Customer
• Local Branch Official
• Maintenance Engineer

The following are the use cases that directly support this vision. Additional use cases may be identified later that are needed to support this or that technology or to support the use cases listed here. They should not be added to this list unless they are deemed to directly support the vision as described in this document.

• Audit
• Customer Uses Machine
• Maintain Machine

4.5.2. Identifying Actors and Use Cases

For the ATM case study, we will elaborate on the examples in Section 4.3, “Salida del Proceso de Captura de Requerimientos”, Figure 4.4, “Diagrama de caso de uso para un sistema de Cajero Automático mostrando relaciones de inclusión”, and Figure 4.5, “Diagrama de casos de uso para un sistema de Cajero Automático mostrando una relación de extensión.”, and progress to identify additional actors and use cases that comprise our model of the ATM system. Figure 4.4, “Diagrama de caso de uso para un sistema de Cajero Automático” exemplified the essential concepts and components of a use case diagram such as, use cases, actors, multiplicity, and include / extend relationships. They showed the relationships between the actors and use cases, and demonstrated how these actors and use cases interact.

In Figure 4.4, “Diagrama de caso de uso para un sistema de Cajero Automático mostrando relaciones de inclusión”, we see a use case diagram for an ATM system consisting of “Maintain Equipment” and “Reload ATM”. Use ATM was further defined in terms of the behavior of three simpler use cases: “Deposit Cash”, “Withdraw Cash” and “Query Account”.

Chapter 5. Analysis

Analysis is the process of taking the “customer” requirements and re-casting them in the language of, and from the perspective of, a putative solution.

We are not actually trying the flesh out the detailed solution at this stage. That occurs in the Design Phase (see Chapter 6, Design).

Unlike the boundary between Requirements and Analysis Phases, the boundary between Analysis and Design Phases is inherently blurred. The key is that analysis should define the solution no further than is necessary to specify the requirements in the language of the solution. The artifacts in Analysis generally represent a high level of abstraction.

Once again the recursive, and iterative nature of our process means we will come back to the Analysis phase many times in the future.

5.1. The Analysis Process

There are three schools of thought on how Analysis should be approached. The ontologist defines the data (actually the metadata) first and worries about processes later. The true ontologist would prefer not to have to think about processes at all. The phenomenonologist reverses this and favors process over data. The panparadigmist considers both process and data to be equally important and addresses both from the start.

When it comes to being a purist the ontologist has the upper hand. It is possible to define and build a database into which data can be entered and retrieved without concern for what happens to it or is done with it. On the other hand implementing a process without having any data structures for it to operate on is not very meaningful.

5.1.1. Class, Responsibilities, and Collaborators (CRC) Cards

The CRC methodology favors the phenomenonologists preference for analysis. It is the equivalent of starting with the use cases, the process aspects (operations) of the class diagrams, and scenarios from which sequence diagrams can be initiated.

CRC cards and the associated methodology are described in detail in Appendix G, The CRC Card Methodology. They are used again in the design phase and are further discussed in Chapter 6, Design.

The strength of CRC cards during analysis.

• Common Project Vocabulary -
• Spread Domain Knowledge -
• Making the Paradigm Shift -
• Live Prototyping -
• Identifying Holes in Requirements -

In this phase the group should consist of two or three domain experts, one object-oriented technology facilitator, and the rest of the group made up of people who are responsible for delivering the system.
The first time that the Analysis phase occurs a special case of the CRC session happens as there are no classes or scenarios to choose from to define a CRC session. At this point a special type of session known as brainstorming is held. During this session you identify the initial set of classes in the problem domain by using the problem statement or requirements document or whatever you know about the desired result for a starting point. The nouns that are found in whatever you are starting from are a good key to an initial set of classes in the system. In a brainstorming session there should be little or no discussion of the ideas. Record them and filter the results after the brainstorming. At this stage the distinction between class and object is blurred.

Once a reasonable set of classes has been defined by the group, responsibilities can be added. Add responsibilities that are obvious from the requirements or the name of the class. You don't need to find them all (or any for that matter). The scenarios will make them more obvious. The advantage of finding some in the beginning is that it helps provide a starting place.

Select the initial scenarios from the requirements document by examining it's verbs in much the same way that we scanned its nouns earlier. Then as many walk through sessions as necessary to complete the analysis phase are performed.

When is enough of the analysis complete that design can begin? When all the different responsibilities are in place and the system has become stable. After all the normal behavior has been covered, exceptional behavior needs to be simulated. When you notice that the responsibilities are all in place to support the new scenarios, and there is little change to the cards, this is a sign the you are ready to start design.

5.10. Case Study (To be written)

Regardless of which methodology you use, at this time you are undoubtedly going to take the problem statement from Section 4.5, “Case Study” and extract the nouns from it. This list should be compacted to contain only those nouns that are expected to result in a class. This effort results in the following.

• Account
• Audit trail
• Bank
• Cash
• Customer

5.10.1. CRC Cards

The project manager convenes a CRC session at which the initial set of classes are to be defined. The facilitator reminds the participants that we are in the analysis phase and are only interested in what needs to be done (at the business level) and are to leave out anything that smacks of how to do it. As a general rule of thumb this means a subset of the nouns from the problem statement (see above). The group starts with a complete list of all of the nouns in the statement, examines each one, and decides which are inappropriate crossing them off the list. Each class is then assigned to one of the participants.

Chapter 6. Design

We now have the problem we are trying to solve specified in the language of a putative solution. In the Design Phase, we construct all the details of that solution.

The blurred boundary between Analysis and Design is reflected in their use of many of the same UML tools. In this chapter we will mostly be reusing UML technology we have already met once. The big step is casting everything into concrete terms. We move from the abstract concepts of analysis to their concrete realization.

Once again the recursive, and iterative nature of our process means we will come back to the Design phase many times in the future.

6.1. The Design Process (To be written)

6.1.1. Class, Responsibilities, and Collaborators (CRC) Cards

Strength of CRC cards during Design

- Spreading Objet-Oriented Design Expertise
- Design Reviews
- Framework for Implementation
- Informal Notation
- Choice of supporting software components
- Performance Requirements

In this phase developers replace some of the domain experts in the group, but there should always be at least one domain expert in the group.

The focus of the group moves from what is to be done to how to do it. The classes from the solution domain are added to those defined in the analysis phase. Think about what classes are needed to make the system work. Do you need a List class to hold objects? Do you need classes to handle exceptions? Do you need wrapper classes for other subsystems? New classes that are looked for in this part, are classes that support the implementation of the system.

During the design phase the distinction between class and object becomes important. Think about the objects in your scenarios. Who creates the objects? What happens when it is created and destroyed? What is the lifetime of the object vs. the lifetime of the information held be the object?

Now is the time to look at what information the objects hold compared to what is requested from other classes or computed on the fly. Use the back of the card to record the attributes found for the classes. Break you responsibilities into subresponsibilities and list the subresponsibilities indented under the main responsibilities. Move the collaborators next to the subresponsibilities that use them.

After the Collaborator class on your card list the responsibility of the used class that is used in the collaboration. After the collaborating responsibilities on your cards, list the data passed back by the collab-
orating object in parenthesis.

Redo the scenarios you did in the analysis phase, but now take into consideration all of the design heuristics discussed. Make up your own scenarios and try them.

6.5.3. Advanced Class Features

6.5.3.1. Operations on Interfaces

6.5.3.1.1. Interfaces that extend interfaces

Add a unnamed interface to the current classdiagram by single-clicking on the interface icon in the tool bar and then clicking at the diagram pane (see Figure 6.1, “Selecting the Interface tool”).

Figure 6.1. Selecting the Interface tool

Then double click on the interfaces name field to change it's name as shown in Figure 6.2, “Interface artifact on the Class Diagram”.

Figure 6.2. Interface artifact on the Class Diagram

and type a name for it (like TestInterface in this case). Press “Enter” when the name is complete.

(You could also enter the name by going to the Properties Tab in the Details Pane after adding the interface.)

Add another interface with a different by repeating the last 2 steps. Then single-click on the Generalization icon in the tool bar as shown in Figure 6.3, “Generalization on the Class Diagram tool bar”.

Figure 6.3. Generalization on the Class Diagram tool bar

move the mouse pointer to the subinterface, press the left mouse button and drag the generalization to the superinterface, where you release the mouse button. Figure Figure 6.4, “Generalization between two Interfaces.” shows how your diagram should look now.

Figure 6.4. Generalization between two Interfaces.

By clicking on the subinterface and the source tab properties pane, and then selecting Java Notation for the source tab, you can see that the interface actually extends it's superinterface.

Chapter 7. Code Generation, Reverse Engineering, and Round Trip Engineering

7.1. Introduction

We now have our design fully specified. With the right simulator we could actually execute the design and see if it works. (ArgoUML does not provide such functionality, but this functionality has been provided in alternative tools.)

ArgoUML does allow you to generate code from the design in several different programming languages. We, most likely, already in the design had a programming language in mind because some of the design considerations are to care for a specific language.

The output of this process is the set of files that constitute the program that solves the problem.

Once again the recursive, and iterative nature of our process means we will come back to the Build phase many times in the future.

There is also another side to this and that is the reverse engineering side. If we happen to have an old program that we would like to examine then we could take the files and reverse engineer them to create a design. This can be used when trying to understand some not so well documented program or as a quick start for the design work.

The process of going back and forth between doing changes in the design followed by a code generation and then doing changes in the code followed by a reverse engineering using for every change, the best possible perspective, is called Round-trip Engineering.

7.2. Code Generation

The output of the Code Generation is the completed program. Depending on the contents of the design, we could also generate Unit test cases.

To do the work we need the design model, containing both static and dynamic descriptions of the program.

7.2.1. Generating Code from the Static Structure

It is rather straightforward to do this generation, at least as long as we do it for an object-oriented language. This is some of the basic rules:

- A class will become a class.
  
  In some target languages (like java, c++) they also become files and compilation units.

- A generalization will become an inheritance.

  If the target language does not support inheritance and we didn't address this during the design, some special conversions are required to solve this.
• An attribute will become a member variable.

• A navigable association will become a member variable.

Depending on the target language, target platform, and the association multiplicities this will be a pointer, a reference, a collection class, an entry in some table or map.

• A non-abstract operation in a class will become a method.

• An abstract operation in a class will become an abstract method.

• An in parameter in an operation will become a parameter in the method.

For simple types (int, boolean), this is the normal case. For C++, these will probably const classes. For Java, this cannot be enforced for classes.

• An out or in/out parameter in an operation will become a referenced parameter in the method.

For C++, these will be referenced non-const parameters. For Java classes, this is the default. Simple types (int, boolean) must, in java, be converted to an object of a corresponding class (Integer, Boolean).

• The visibilities of the attributes, associations, and operations will become visibilities on the member variables or methods.

• Packages will become directories, namespaces, or both.

7.2.2. Generating code from interactions and state machines

This conversion is not as straightforward as the conversion of the static structure. It is much more depending on the target language and target platform.

In general it is only possible to say the following for interactions:

• A message is converted into a function call.

  The class of the recipient will have to have a function with the correct name and signature.

  The sender function in the class of the sender will have a call to the function in the recipient.

• An asynchronous message is converted to either posting a message to be handled by some other thread or a function call to a function that starts a new thread.

The following describes one possible way to generate state machines:

• A State Machine is generated to a set of member variables that each method in this class refer to when deciding behavior.

• A State is generated to a closed set of combination of values on these member variables.

• An Event is generated as a call to a member method that can change the state.

  These methods would then typically have one big switch statement splitting on the current state.
• A Guard is generated to an if statement in the event member method in the branch for the correct state.

• A Transition is generated as an assignment of some state variable.

• An Action is generated as a function call.

### 7.3. Code Generation in ArgoUML

#### 7.3.1. Static Structure

Most of the generation can be done automatically by the provided language modules. Files are generated in a directory hierarchy that need to be filled in by the actual code.

#### 7.3.2. Interactions and statechart diagrams

There is currently no support for this in ArgoUML, not for any language.

### 7.4. Reverse Engineering

Reverse Engineering is used for two main purposes:

1. To get previously developed classes into the model to build upon.
2. To get a UML view of previously developed classes to understand how they work.

Essentially this does the opposite of Code Generation.

### 7.5. Round-Trip Engineering

Round-Trip Engineering makes it possible to switch perspective while doing the design. Create some classes in a class diagram. Write some code for some of the operations or functions using your favorite editor. Move the operations from one class to another in the class diagram...

ArgoUML currently does not support this for any language.
Part 2. User Interface Reference
Chapter 8. Introduction

This chapter describes the overall behavior of the user interface. Description of the various component parts—the menu bar, panes and various diagrams—is in separate chapters.

8.1. Overview of the Window

Figure 8.1, “Overview of the ArgoUML window” shows the main ArgoUML window.

The titlebar of the window shows the following 4 parts of information, separated from each other by a dash.

- The current filename. If no filename for the project is set yet, then the titlebar shows “Unititled”.
- The name of the currently active diagram.
- The name “ArgoUML”.
- An asterisk (*). This item is only present if the current project file is “dirty”, i.e. it is altered, but not yet saved. In other words, if the asterisk is absent, then the current file has not been altered.

Figure 8.1. Overview of the ArgoUML window

At the top of screen is a menu bar, which is described in Chapter 10, The Menu bar. Below that is the toolbar, as described in Chapter 9, The Toolbar.

The bulk of the window comprises four sub-windows or panes. Clockwise from top left these are the explorer (see Chapter 11, The Explorer), editing pane (see Chapter 12, The Editing Pane), details pane (see Chapter 13, The Details Pane) and to-do pane (see Chapter 14, The To-Do Pane). All 4 panes have a toolbar at the top (in the details pane it is located under the properties tab). An overview of the panes is given in Section 8.3, “General Information About Panes”. Finally at the bottom of the window is a status bar described in Section 8.4, “The status bar”.

8.2. General Mouse Behavior in ArgoUML

Mouse behavior that is specific to the various panes of ArgoUML (see Section 8.3, “General Information About Panes”) or the menu bar, is discussed in the chapters covering those panes and the menu bar. In this section we cover behavior that is general across all of ArgoUML.

In a number of places in ArgoUML text may be directly edited (for example the constraint editor—see Section 13.7.1, “The Constraint Editor”). The behavior of the mouse when handling text is discussed in the sections that follow.

8.2.1. Mouse Button Terminology

ArgoUML assumes a two button mouse. We will refer to the buttons as “button 1” and “button 2”. Button 1 is the leftmost button on a right-handed mouse, and sometimes referred to as the select button. Button 2 is the rightmost button on a right-handed mouse, and is sometimes referred to as the adjust button.

A single depress and release of a mouse button with the mouse is referred to as a click. Two clicks in
quick succession is referred to as a **double click**. Moving the mouse while holding a button down is referred to as **button motion** with the starting point being at **button down** and the end point at **button up**.

### 8.2.2. Button 1 Click

Clicking on an user-interface object or on a diagram artifact may establish many different things. Most of the behaviour is experienced quite intuitive by the user, mainly because the high degree of standardisation, even spanning different computer platforms (Macintosh, PC, UNIX,...). ArgoUML follows the *Java Look and Feel Design Guidelines* by Sun. See [http://java.sun.com/products/jlf/](http://java.sun.com/products/jlf/). Hence, behaviour of common user-interface components is generally not discussed in this document.

On the other hand, mouse actions in a diagram may not seem so intuitive to the user, since it is specific for ArgoUML. Hence they are explained here. In short, clicking selects or activates the object beneath the mouse-pointer, and moves the focus (i.e. navigation).

More in detail, the button 1 click may cause the following result:

#### 8.2.2.1. Selection

Here button 1 is used to choose (select) an artifact (in a list or tree or on a diagram) on which subsequent operations will take place. Multiple artifacts may be selected by using Shift and/or Ctrl in combination with button 1, see Section 8.2.5, “Shift and Ctrl modifiers with Button 1”. Selection is always clearly indicated by a colored background.

On a diagram, the selected artifact is indicated with colored "blocks" at the corners/ends of the object. Artifacts can be selected or deselected in different ways:

- **Button 1 click.** Deselects all artifacts, and selects the one clicked on.
- **Button 1 motion.** Button motion (moving the mouse with the button down) in the diagram, not on any artifact, allows to draw a rectangle around artifacts which will be selected when the button 1 is released.
- **Menu functions and shortcuts.** Many menu operations change selection as side-effect, e.g. creating a new diagram. Many keyboard shortcuts for menu operations change the selection, e.g. Ctrl-A, which stands for the **Select All** function.

#### 8.2.2.2. Activation

Here button 1 is used to activate the user interface component, e.g. a button. The object is usually highlighted when the mouse button is pressed and then activated when the mouse button is released. Activating an user-interface object means that its function is executed.

#### 8.2.2.3. Navigation

Here button 1 is used to move the focus from one user interface component or diagram artifact to another. It is better known under the term keyboard focus. This because keyboard commands usually work on the artifact that has the focus. The focus is indicated by a (hardly visible) box around the artifact, or for a text entry box, by a flashing cursor.

#### 8.2.2.4. General Behavior When Editing Text

Here button 1 is used to select the point within the text at which operations (text entry and deletion) will take place.
8.2.3. Button 1 Double Click

The behavior of button 1 double click varies between panes and is discussed in their chapters.

8.2.3.1. General Behavior When Editing Text

Here button 1 double click is used to select a complete word, or other syntactic unit within the text. Subsequent operations (text entry and deletion) will replace the selected text.

8.2.4. Button 1 Motion

8.2.4.1. General Behavior When Editing Text

Here button 1 motion is used to select a range of text. Subsequent operations (text entry and deletion) will replace the selected text.

8.2.5. Shift and Ctrl modifiers with Button 1

8.2.5.1. Within Lists

This behavior applies where there is a list of things that may be selected. This includes various dialog boxes, and the to-do pane, where there is a list of to-do items to be selected.

Where selections are to be made, the SHIFT key is used with button 1 to extend from the original button 1 selection to the current position.

Similarly the CTRL key with button 1 is used to add individual items to the current selection. Where Ctrl-button 1 is used on an item already selected, that item is removed from the selection.

Caution

Users of Microsoft Windows might be familiar with the use of SHIFT-CTRL-Click (i.e. holding both the Shift and Ctrl key down when clicking), to add sub-lists to an existing selection. ArgoUML does not support this. SHIFT-CTRL-Click will behave as CTRL-Click.

8.2.5.2. General Behavior When Editing Text

In a number of places in ArgoUML text may be directly edited (for example when naming a model element in the properties pane, or when typing a UML note / comment). Here SHIFT button 1 is used to select a range of text from the previously selected point. Subsequent operations (text entry and deletion) will replace the selected text.

8.2.6. Alt with Button 1: Panning

When holding down the Alt key during button 1 down on a diagram, movement of the mouse pans the drawing area. The function is indicated by the mousepointer which turns into a crosshair with arrows.

8.2.7. Ctrl with Button 1: Constrained Drag

When holding down the Ctrl key while dragging with mouse button 1 down on a diagram, the movement of the dragged element element will be constrained to one of eight cardinal directions: North, South, East, West, NE, SE, SW, NW.
8.2.8. Button 2 Actions

Button 2 actions are all dependent on the pane or menu bar, and discussed in their various chapters.

8.2.9. Button 2 Double Click

Button 2 actions are all dependent on the pane or menu bar, and discussed in their various chapters.

8.2.10. Button 2 Motion

Button 2 actions are all dependent on the pane or menu bar, and discussed in their various chapters.

8.3. General Information About Panes

The four sub-windows of the main ArgoUML window are called panes. Clockwise from top left these are the explorer (see Chapter 11, The Explorer), editing pane (see Chapter 12, The Editing Pane), details pane (see Chapter 13, The Details Pane) and to-do pane (see Chapter 14, The To-Do Pane). At the top the editing pane is a tool bar.

8.3.1. Re-sizing Panes

You can re-size panes by dragging on the divider bars between them. To indicate this possibility, the mouse cursor changes shape when hovering over the divider bars.

In addition you will see there are two small left pointing arrows within the vertical divider bars, one at the top of the vertical divider bar between explorer and editing pane and one at the top of the vertical divider bar between to-do pane and details pane. Button 1 click on the first of these will expand the editing pane to the full width of the window, button 1 click on the second will expand the details pane to the full width of the window.

There is also a small downward pointing arrow within the horizontal divider bar at its leftmost end. Clicking on this will expand the explorer and editing panes to the full depth of the window.

By using both the top arrow on the vertical divider and the arrow on the horizontal divider, it is possible to expand the editing pane to use the entire window.

The original configuration can be restored by clicking again on these arrows, which are now located at the edge of the window.

8.4. The status bar

The status bar is at the very bottom of the ArgoUML window and is used to display short advisory messages. In general such messages are self explanatory. It is e.g. used for displaying parsing error messages in case a text entered on the diagram can not be interpreted.
Chapter 9. The Toolbar

9.1. File operations

These buttons have identical functions as their counterparts in the File menu.

• New See for a full description Section 10.3.1, “New”.
• Open Project... See for a full description Section 10.3.2, “Open Project...”.
• Save Project See for a full description Section 10.3.3, “Save Project”.
• Print See for a full description Section 10.3.10, “Print...”.

9.2. Edit operations

These buttons have identical functions as their counterparts in the Edit menu.

• Remove From Diagram See for a full description Section 10.4.2, “Remove From Diagram”.
• Navigate Back See for a full description Section 10.4.1, “Select”.
• Navigate Forward See for a full description Section 10.4.1, “Select”.

9.3. View operations

The Find... button has identical behaviour as its counterpart in the View menu. The Zoom button is a more luxuriously version of the function in the View menu.

• Find... See for a full description Section 10.5.2, “Find...”.
• Zoom This is a different version of the menu-item for zooming, as described in Section 10.5.3, “Zoom”. Clicking with button 1 on the zoom-icon opens a panel as in the figure below.

Figure 9.1. The Zoom slider on the Toolbar

Once the panel is open, the following actions are possible:

• Clicking with button 1 on the "knob" followed by button 1 movement will adjust the zoomfactor.
• Clicking with button 1 on the shown percentage allows editing the given zoomfactor (in percent) directly with the keyboard. Double clicking on the value shown selects the whole entry for easy overtyping.
• Clicking with button 1 below or above the knob increases or decreases the zoom factor with 1%. Use this function to easily fine-adjust the percentage.
• Clicking with button 1 or button 2 on the Zoom tool, or anywhere outside the slider panel closes the
panel.

- The keyboard can be used to operate the Zoom Slider as follows: When the Zoom icon in the tool-
bar has the focus (indicated by the thin blue box around it), then pressing the spacebar opens the
zoom slider panel. Use the arrow keys to increase and decrease the percentage 1 by 1. Use Shift-
Tab to set the focus to the percentage box, where you can edit the given value directly. Pressing
Enter activates the changed value. When the "knob" has the focus, pressing PageUp/PageDown
increases/decreases the percentage by 50. Pressing Home sets the percentage to 500%, and End
sets it to 0%.

### 9.4. Create operations

These buttons have identical functions as their counterparts in the Create menu.

- **New Use Case Diagram** See for a full description Section 10.6.1, “New Use Case Diagram”.
- **New Class Diagram** See for a full description Section 10.6.2, “New Class Diagram”.
- **New Sequence Diagram** See for a full description Section 10.6.3, “New Sequence Diagram”.
- **New Collaboration Diagram** See for a full description Section 10.6.4, “New Collaboration
  Diagram”.
- **New Statechart Diagram** See for a full description Section 10.6.5, “New Statechart Diagram”.
- **New Activity Diagram** See for a full description Section 10.6.6, “New Activity Diagram”.
- **New Deployment Diagram** See for a full description Section 10.6.7, “New Deployment Dia-
  gram”.
Chapter 10. The Menu bar

10.1. Introduction

An important principle behind ArgoUML is that actions should be able to be invoked in whatever way the user finds convenient. As a result many (but not all) actions that can be carried out on the menu can be carried out in other ways as well under ArgoUML.

A number of the common menu entries are also available through keyboard shortcuts.

It is also possible to navigate the menu from the keyboard. Each level of each menu is identified by a letter (shown underlined in the menu or entry name from the moment the ALT key is pressed). This sequence of letters while holding down the ALT key selects the entry.

The following is an explanation of why the menu items are grouped as they are.

- The File menu contains operations that affect on the whole project/file. All the items in this menu can be explained as such.

- The Edit menu is generally intended for editing the model or changing the content of a diagram. It also contains functions to enable editing, like e.g. selecting. This menu is not intended for diagram layout functions. Most functions here do something with the selected model element and diagram. The items "Configure Perspectives..." and "Settings..." are a bit different, since they adjust the way ArgoUML works - but they do not belong in the File menu, since their settings are not stored in the project.

- The View menu is for functions that do never alter the model, nor the diagram layout, only the way you view the diagram. A good example is "zoom". Also navigational functions belong here, e.g. "Find" and "Goto Diagram...". All changes of settings in this menu apply to all diagrams (e.g. zoom).

- The Create menu contains all possible diagrams that can be created. These functions are context dependent, since they work on the selected model element.

- The Arrange menu allows layout changes in the current diagram, which is not the same as the items in the View menu. Functions here can not alter the UML model.

- The Generation menu is for Code Generation. The functions here work either on the selected model elements, or on the whole project.

- The Critique menu is specific for settings related to critics, which apply for all projects.

- The Tools menu is currently empty. If plugins are installed, then their functions appear here.

- The Help menu contains the usual "information" and "about".

10.2. Mouse Behavior in the Menu Bar

Behavior of the mouse in general, and the naming of the buttons is covered in the chapter on the overall user interface (see Section 8.2, “General Mouse Behavior in ArgoUML”). There is no ArgoUML specific behaviour for the menu.
10.3. The File Menu

These are actions concerned with input and output and the overall management of projects and the ArgoUML system.

10.3.1. New

Shortcut Ctrl-N.

This initializes a new project within ArgoUML. The project is created without a name. It contains a (top-level) Model named untitledModel and two empty diagrams: a class diagram and a use case diagram.

Caution

untitledModel is not a conventional model name (most processes suggest models should be created from lower case letters). ArgoUML permits you to use any case letters, but a critic will trigger to warn that this is not conventional. See Section 16.2, “The Model” for a discussion of this.

If the model has been altered (as indicated by the "*" in the titlebar of ArgoUML's window), then activating the "New" function is potentially not the user's intention, since it will erase the changes. Hence a confirmation dialog appears to allow the user to save his work first, or cancel the operation completely.

Figure 10.1. The confirmation dialog for New.

10.3.2. Open Project...

Shortcut Ctrl-O.

This opens an existing project from a file. Selecting this menu option will open a file selection dialog (see Figure 10.2, “The file selection dialog for Open Project...”).

Figure 10.2. The file selection dialog for Open Project....

The main body of the dialog is a text area with a listing of all directories and files in the currently selected directory which match the current filter (see below).

Navigating in the directory tree is possible by selecting a directory in the drop down selector at the top of this dialog. Navigating deeper in the tree may be done by double clicking button 1 on the directory shown in the main text area.

In the lower portion of the dialog is a text box labeled File name: for the name of the file to be opened. The file name may be typed directly in here, or selected from the directory listing above using button 1 click.

Beneath this is a drop down selector labeled Files of type: to specify a filter on the files to be shown in the directory listing. Only files that match the filter are listed. The available filters are listed below. The default filter is the first one, which combines all available formats.
10.3.3. Save Project

Shortcut Ctrl-S.

This saves the project using its current file name. Use Save Project As... to save the project to a different file. If no filename is given yet (e.g. after New), then this function works exactly as Save Project As....

Note

In certain circumstances, there is nothing to save, and this menuitem is downlighted. E.g. when the user did not yet alter a loaded project. The presence of a “*” in the titlebar of ArgoUML's window indicates that the current project is “dirty” (has been altered), and can be saved.

10.3.4. Save Project As...

This opens a dialog allowing you to save the project under a different file name (or to specify a file name for the first time if the project is a new project).

The dialog box is almost identical to that for Open Project (see Figure 10.2, “The file selection dialog for Open Project....”). The extension of the filename is automatically set.

10.3.5. Revert to Saved

This menu-item allows you to throw away all your recent changes, and reload the last saved version of the current project. It works a bit like an Undo feature, but only restores changes done since the last time the file was saved.

This menu-item is downlighted unless the current project has been saved or loaded before (i.e. it has a name), and it has been altered.

When this menu-item is activated, a small confirmation dialog box opens, as shown in the figure below. This warning that all recent changes will be discarded, is needed because the action can not be undone. Selecting No cancels the whole action as if you did not select the menu-item in the first place. Selecting Yes reloads the last saved file.

Figure 10.3. The warning dialog for Revert to Saved.
10.3.6. Import XMI...

This menu-item allows to load an UML 1.3 or 1.4 model which was exported by e.g. another tool, as a XMI file, according the XMI V1.0, V1.1 or V1.2 standard. The extension of such file should be .xmi.

If the model has been altered (as indicated by the "*" in the titlebar of ArgoUML's window), then activating the "Import XMI..." function is potentionally not the user's intention, since it will erase the changes. Hence a confirmation dialog appears to allow the user to save his work first, or cancel the operation completely.

Figure 10.4. The confirmation dialog for Import XMI....

When the menu is activated, the standard filechooser appears, see Figure 10.5, “The dialog for Import XMI...”. Beware the fact that this file will only contain the model, not any diagram layout. Hence, the new project will not contain any diagrams.

Figure 10.5. The dialog for Import XMI....

10.3.7. Export XMI...

This menu-item allows to save the complete structure of the UML 1.4 model as a XMI file, according the XMI V1.2 standard. Beware the fact that this file will only contain the model, not any diagram layout. Hence, if the XMI file is reloaded with the File - Open Project... menu, then the diagrams are lost.

When the menu is activated, the standard filechooser appears, see Figure 10.6, “The dialog for Export XMI...”.

Figure 10.6. The dialog for Export XMI....

10.3.8. Import Sources...

A very powerful feature of ArgoUML is that it can “Reverse Engineer” Java code to yield a class diagram. This sub-menu entry specifies Java code to be imported for reverse engineering.

The dialog box is similar to that for Open Project (see Figure 10.2, “The file selection dialog for Open Project...”), but with two extra tabs placed alongside the directory listing, as shown in Figure 10.7, “The file selection dialog for Import Sources....”.

Figure 10.7. The file selection dialog for Import Sources....

Those fields that are the same as Open Project behave in the same way (see Section 10.3.2, “ Open Project...”).

Next to the "All Files" file filter, there is the default filter "Java Source File (*.java)".
The first of the two tabs is labeled General and is selected by button 1 click on its tab. It provides a combo box for the language selection (in V0.18 of ArgoUML only Java can be chosen), and the following selections:

- Descend directories recursively. If enabled (the default), reverse engineering will track through sub-directories for any further Java files. If not it will restrict to the selected directory.
- Changed/new files only. If enabled (the default), only changed and new files are imported. If not all classes will be replaced.
- Create diagrams from imported code. If you unselect this, then no diagrams are created, i.e. all data will only be visible in the explorer.
- Minimise Class icons in diagrams. If enabled, then the attributes and operations compartments will not be shown in the classes on the generated class diagrams. Note: This item is checked by default, and is overseen by many users, which are then surprised by the result.
- Perform Automatic Diagram Layout. If selected, then ArgoUML will do its best to layout the generated diagrams automatically. If not, then all items will be placed at the top left corner of the diagram.
- Level of import detail: Classifiers only / Classifiers plus feature specifications / Full import. The latter is the default.
- Import source file encoding: The value Cp1252 is often the default. This string represents the coded character set identifier (CCSID).

The second of the two tabs is labeled Java and is selected by button 1 click on its tab. It provides two pairs of radio boxes.

- The first radio box allows selection between modeling attributes of Java classes as UML attributes (the default) or as UML associations to the class specified.
- The second radio box allows selection between modeling arrays as new datatypes in their own right (the default) or as their base datatype with multiplicity.

10.3.9. Page Setup...

This brings up the standard dialog box provided by the operating system to adjust printer paper size, orientation, and other options.

10.3.10. Print...

Shortcut Ctrl-P.

This brings up the standard dialog box provided by the operating system allowing the current diagram to be printed out.

In some cases, when the printing is started, the dialog box of Figure 10.8, “The diagram exceeds page size dialog.” appears. Selecting the “Fit to page” button does print the whole diagram fitted on one page by scaling it down. Which might cause all text to be too small to read in case of big diagrams, but it is a quick and easy way to get an usable printout. Selecting the “Multiple pages” option does print unscaled, by dividing the diagram in pieces, on as many pages as needed. Pressing the close button of the dialog does the former option.
Warning

If the current diagram contains no selected artifacts, then the whole diagram is printed. However, if one or more artifacts are selected, then only the area they cover is printed! If scaling is selected (by the "Fit to page" choice in the dialog box described above), then the scaling is done on basis of the selected artifacts only. If scaling is not chosen (or in case it is not needed), then all pages containing a selected artifact are printed.

10.3.11. Export Graphics...

This menu entry brings up a dialog box allowing the currently selected diagram (in the editing pane) to be saved in one of a number of graphic formats.

The dialog box is identical to that for Open Project (see Figure 10.2, “The file selection dialog for Open Project...”), except for the Files of type: The chosen filetype specifies the graphics format used for saving. The filename is automatically extended with the corresponding ending (if not entered already). A default filename is generated based on the diagram name.

The available graphics types are:

- GIF image (*.gif)
- Encapsulated Postscript file (*.eps)
- PNG image (*.png)
- Postscript file (*.ps)
- Scalable Vector Graphics file (*.svg)

The graphics format that is selected by default is set in the dialog under the menu entry Edit - Settings...

10.3.12. Export All Graphics...

This menu entry brings up a dialog box to select a directory. In this directory, for all diagrams in the current project, a graphics file is generated.

The names of the files are deducted from the diagram names. The graphics format that is produced is set in the dialog under the Edit menu (see Section 10.4.5, “Settings...”).

10.3.13. Notation

This sub-menu presents a radio button selection for notation, i.e. the language in which all textual adornments are shown on the diagrams.

This feature defines the project's notation language.

There are 2 ways to set the notation language:
• In the Edit menu, see Section 10.4.5.5, “Notation Tab” in the notation tab of the settings dialog, which defines the default notation language for new projects. This choice is stored in the argouml.properties file.

• In the File menu, item Notation. This determines how all textual adornments of figures on all diagrams of the current project are shown. This choice is stored in the project file.

The following 2 notations are build in ArgoUML:

• **UML 1.4.** Uses UML notation as the default notation for every modelelement on any diagram.

• **Java.** Uses Java notation as the default notation for every modelelement on any diagram.

The following choices are only available if the corresponding plugin languages are installed.

• **Cpp.**

• **CSharp.**

• **PHP.**

*Besides UML, only Java is partly implemented in V0.22 of ArgoUML.*

### 10.3.14. Properties

This menu entry brings up a dialog box, which allows the user to set various options of the currently loaded project.

All settings in this dialog are stored in the project-file together with the model.

**Figure 10.9. The dialog for Properties - Notation: The User tab.**

In the User tab, you are able to set the following fields:

• The first field contains the name of the author or responsible for the current project. By default the name and email of the creator are filled in, so probably you will never need to edit this, but it is possible.

• The Project Description field may contain any text that you need to describe the project. By default it is empty.

• The "Last saved with ArgoUML" field indicates the version of ArgoUML that was used to save this project (the last time it was saved). This may be usefull if multiple designers have different versions of ArgoUML, which may not be backwards compatible all the time.

**Figure 10.10. The dialog for Properties - Notation: The Notations tab.**
In the Notations tab, you are able to set the following fields:

- The first field is a combobox that allows selection of the project's Notation language. By default, it lists UML and Java, but other languages may be added by plugins. See the chapter on Notation for more explanation: Section 12.10, “Notation”.

- Use guillemots (?? ??) for stereotypes (clear by default). By default ArgoUML uses pairs of less than and greater than (<< >>) characters for stereotypes. If this box is checked stereotypes on diagrams are shown between true guillemots (?? ??).

  This feature is presumably added to ArgoUML because guillemots are poorly supported by various fonts, and if they are present, then they are quite small and poorly visible.

- Show visibility (clear by default). If this is selected, then ArgoUML will show the visibility indicators in front of e.g. attributes in the diagram. In UML the notation is "+" for public, ";-" for private, "#" for protected, and "~" for package. E.g. for an attribute, it may show: +newAttr : int.

- Show multiplicity (clear by default). If this is selected, then ArgoUML will show the multiplicity of e.g. attributes in the diagram. In UML notation, the multiplicity is shown between [], such as: +newAttr [0..*] : int. This setting has no impact on showing multiplicity near association-ends.

- Show initial value (clear by default). If this is selected, then ArgoUML will show the initial value of e.g. attributes in the diagram. In UML notation, the initial value is shown e.g. like this: +newAttr : int = 1.

- Show properties (clear by default). If this is selected, then ArgoUML will show various properties between braces {}. E.g. for an attribute, it may show: +newAttr : int { frozen }.

- Show types and parameters (set by default). When this checkbox is unmarked, attributes in classes are shown without type indication, and operations are shown without parameters. This feature may be useful during the analysis phase of your project. If all checkmarks in the Notation Tab are unchecked, then e.g. for an attribute, ArgoUML may show: newAttr. And for an operation: newOperation().

- Show stereotypes in explorer (clear by default). If this is selected, then ArgoUML will show stereotypes next to the icons of the modelelements in the Explorer, i.e. the tree structure at the left hand side.

- Default shadow width (set to 1 by default). ArgoUML is able to draw all elements on a diagram with a shadow, for esthetical reasons. Use this setting to adjust the size of the shadow, used when the modelelement is created. The details tab "Presentation" allows to set the shadow per modelelement, after they are created, but ArgoUML V0.22 does not retain this latter change after save and load.

10.3.15. Save Configuration

ArgoUML has various user specific configurations that can be set, through the Settings... entry on the Edit menu (see Section 10.4.5, “Settings...”) or directly on the various panes. Also the main window size and location is such a setting. Activating this menu entry causes the information to be saved in the file argo.user.properties. The location of this file is in the "users home directory", which is defined as ${user.home}, and can be determined as described in Section 10.4.5.2, “Environment Tab”.

Tip

79
10.3.16. Most Recent Used Files

ArgoUML remembers a few of the most recently saved files, and lists them here, to enable loading then in the most simple way.

The maximum number of files that is listed here, can be adjusted in the Edit -> Settings... menu. The list of files is stored in the argo.user.properties file in the user's home directory.

10.3.17. Exit

Shortcut Alt-F4.

This closes down ArgoUML. A warning message will pop-up if you have a project open with unsaved changes asking if you wish to save it. See Figure 10.11, “The save changes dialog.”. The options are:

- **Yes** (save the project and exit ArgoUML);
- **No** (do not save the project, but still exit ArgoUML); and
- **Cancel** (do not save the project and do not exit ArgoUML).

*The dialog box can also be closed by clicking in the close button in the window border. The effect is the same as selecting “Cancel”.*

Figure 10.11. The save changes dialog.

10.4. The Edit Menu

This menu provides support for selecting artifacts on the editing pane; removal of artifacts from diagrams and the model; and control of user settings.

10.4.1. Select

This sub-menu provides for selection of items on the editing menu. It has the following entries.

- **Select All** (shortcut Ctrl-A). Selects all artifacts on the current pane or in the current field. The exact behaviour depends on the current pane (i.e. the last one you clicked in): explorer pane, editing pane, to-do pane, details pane. One rule applies in all cases though: the selection on the diagram (editing pane) and in the explorer are always synchronised.

  If the editing pane is the current pane: First everything in the explorer and on the current diagram is deselected, and then everything that is on the current diagram is selected (and if the same items appear in the explorer, then they are also there indicated as selected, because they are always synchronised).

  If the explorer pane is the current pane: All visible items in the explorer pane are selected, and
non-visible items are deselected.

If the to-do pane is the current pane: All visible items in the to-do pane are selected, and non-visible items are deselected. In fact, this works the same as for the explorer pane, because both are tree structures.

If the details pane is the current pane: The function only works when the cursor is in certain fields, where selecting is possible, e.g. a Name field. In such a case, the Select All function extends the current selection to the whole field contents.

- Navigate Back. ArgoUML keeps a record of the artifacts that you have been selecting while navigating the model. This button moves you back to the previous one selected. If there are no more previous artifacts, the button is grayed out.

- Navigate Forward. ArgoUML keeps a record of the artifacts that you have been selecting while navigating the model. This button moves you forward to the next one selected (after you have used the Navigate Back button to move back). If there are no more next artifacts, the button is grayed out.

- Invert Selection. This inverts the current selection on the current pane. More exact: everything that was selected is de-selected and everything that was not selected within the current pane is selected.

10.4.2. Remove From Diagram

Shortcut Delete.

This removes the currently selected item(s) from the diagram, but not from the model.

The modelement can be re-added to the diagram by button 2 click on the modelement in the explorer, or by dragging it onto the diagram.

10.4.3. Delete From Model

Shortcut Ctrl-Delete.

This function deletes the selected item(s) from the model completely.

If the item to be deleted is also present on another diagram than the current one, the dialog box from figure x appears.

Figure 10.12. The dialog for confirmation of Remove from Model.

10.4.4. Configure Perspectives...

This menu-item invokes the same dialog as the button at the top of the explorer. See Section 11.5, “Configuring Perspectives”. for a complete description.

10.4.5. Settings...

This menu entry brings up a dialog box, which allows the user to set various options that control the behavior of ArgoUML (see Figure 10.13, “The dialog for Settings - Preferences.”).
Figure 10.13. The dialog for Settings - Preferences.

The options that can be set up on the various tabs are described in the following sections. For each tab there are three buttons at the bottom of the dialog box.

- **OK.** Activating this button (button 1 click) applies the chosen settings and exits the dialog.

- **Cancel.** Selecting this button (button 1 click) exits the dialog without applying any settings changed since the last **Apply** (or since the dialog started if **Apply** has not been used).

- **Apply.** Selecting this button (button 1 click) applies the chosen settings and remains in the dialog.

Closing the dialog (with the close button in the top corner in the border of the window) causes the same effect as **Cancel.**

These settings are saved persistently for use by subsequent ArgoUML sessions.

### 10.4.5.1. Preferences Tab

Selecting the **Preferences** tab (button 1 click on the tab) gives the following options as check boxes.

- **Show Splash Panel** (set by default). If enabled ArgoUML will show a small panel with a picture while starting up.

  **Tip**

  The splash panel can be seen by using the Help menu (see Section 10.11.2, “About ArgoUML”).

- **Preload Common Classes** (set by default). If enabled ArgoUML creates class objects of a number of classes internally during start up so that instantiation is quicker when they are needed.

- **Reload last saved project on startup** (clear by default). Check this item if you always work on the same project, and wish to load it automatically when you start up ArgoUML.

- **Strip (non-standard) diagrams from XMI file during import** (clear by default). Checking this item will tell ArgoUML to ignore the "Diagram" elements when importing XMI files.

  You only need to use this setting, if ArgoUML gives an error while importing your XMI file saying that it encountered unrecognized elements named "Diagram." Some versions of Poseidon are known to create this type of file by default although there’s usually an export option to force them to create standard XMI files.

- **UML Profile file** (/org/argouml/model/mdr/mof/default-uml14.xmi by default).

  This is a read-only field which shows the current profile being used by ArgoUML. If you specified an alternate profile at startup time or a plugin-module installed a different profile, it will display here.

  In the future this will be a settable field that allows you to select different profiles to match different modeling environments (Java, C++, AndroMDA, etc).
10.4.5.2. Environment Tab

Selecting the Environment tab (button 1 click on the tab) lists several environmental items. Note that none of the paths can be altered — these are just a matter of record.

**Figure 10.14. The dialog for Settings – Environment.**

- **Default Graphics Format.** Here you can select the same graphics formats as in the menu Section 10.3.11, “Export Graphics...”. The chosen format is selected by default in the Export Graphics and Export All Graphics menu-items.

- **Graphics Export Resolution.** This allows you to artificially increase the resolution of produced graphics. The advised setting is "Standard". To be able to use "High" or "Extra High", you usually need to start the Java virtual machine with extra memory.

- **${argo.root}.** The full path to the ArgoUML program, i.e. the argouml.jar file.

- **${argo.home}.** The ArgoUML home directory which contains the "jar" files needed by ArgoUML.

- **${argo.ext.dir}.** The directory holding ArgoUML extensions by default the ext sub-directory of the ArgoUML build directory.

- **${java.home}.** The home directory of the Java Runtime Environment (JRE).

- **${user.home}.** The user's home directory. Used for storing the argo.user.properties file.

- **${user.dir}.** The directory from which ArgoUML was started.

- **Startup Directory.** The directory in which ArgoUML starts file searches etc.

10.4.5.3. User Tab

This tab allows the user to record additional information of use to the system. There are two text boxes provided.

**Figure 10.15. The dialog for Settings – User.**

- **Full Name.** Allows the user to record her full name.

- **Email Address.** Allows the user to record his Email address.

This information is used when requesting to-do help by Email.

10.4.5.4. Appearance Tab

This tab allows the user to specify the LAF (Look And Feel) and theme, i.e. what the complete ArgoUML UI looks like. It comprises the following settings.
Figure 10.16. The dialog for **Settings - Appearance**.

- **Look and Feel.** The choice made here influences the complete User Interface. It only becomes effective when ArgoUML is exited and restarted.

- **Metal Theme.** This item is downlighted if the Metal LAF is not chosen. The choice made here influences the complete User Interface. It only becomes effective when ArgoUML is exited and restarted.

- **Smooth edges of diagram lines and text.** This feature is known as “anti-aliasing” on certain platforms. It causes diagonal lines to look much less jagged, by making use of several shades of gray. This feature only works if the operating system supports it.

**10.4.5.5. Notation Tab**

This tab allows the user to specify certain notation settings, i.e. how things are shown on diagrams. It comprises the following check boxes.

All settings here, only define the defaults used for new projects. If you want to change the way the diagrams in your current project look, then see the File - Properties menu.

Figure 10.17. The dialog for **Settings - Notations**.

- **Notation Language** (UML 1.4 by default). This feature allows changing the default notation (i.e. language: UML, Java,...) used on the diagrams for new projects. Suppose that a designer indicates that the default notation of a project is Java. When he saves the project, the choice for Java is stored inside the project file. If someone else is viewing the diagram, he will see the Java notation, too. This person can select the UML notation in the File - Notation menu, and see all diagrams in UML language. See Section 10.3.13, “Notation”).

- **Use guillemots (?? ??) for stereotypes (clear by default).** By default ArgoUML uses pairs of *less than* and *greater than* (<< >>) characters for stereotypes. If this box is checked stereotypes on diagrams are shown between true guillemots (?? ??).

  This feature is presumably added to ArgoUML because guillemots are poorly supported by various fonts, and if they are present, then they are quite small and poorly visible.

  Independent of the way they are shown, when entering stereotypes, you can always type real guillemots (if your keyboard supports it) or their << >> equivalents.

- **Show visibility** (clear by default). If this is selected, then ArgoUML will show the visibility indicators in front of e.g. attributes in the diagram. In UML the notation is “+” for public, “-” for private, “#” for protected, and “~” for package. E.g. for an attribute, it may show: +newAttr : int.

- **Show multiplicity** (clear by default). If this is selected, then ArgoUML will show the multiplicity of e.g. attributes in the diagram. In UML notation, the multiplicity is shown between [], such as: +newAttr [0..*] : int. This setting has no impact on showing multiplicity near association-ends.
• **Show initial value** (clear by default). If this is selected, then ArgoUML will show the initial value of e.g. attributes in the diagram. In UML notation, the initial value is shown e.g. like this: 
  `+newAttr : int = 1`.

• **Show properties** (clear by default). If this is selected, then ArgoUML will show various properties between braces `{}`. E.g. for an attribute, it may show: `+newAttr : int { frozen }`.

• **Show types and parameters** (set by default). When this checkbox is unmarked, attributes in classes are shown without type indication, and operations are shown without parameters. This feature may be useful during the analysis phase of your project. If all checkmarks in the Notation Tab are unchecked, then e.g. for an attribute, ArgoUML may show: `newAttr`. And for an operation: `newOperation()`.

• **Show stereotypes in explorer** (clear by default). If this is selected, then ArgoUML will show stereotypes next to the icons of the modelelements in the Explorer, i.e. the tree structure at the left hand side.

• **Default shadow width** (set to 1 by default). ArgoUML is able to draw all elements on a diagram with a shadow. Use this setting to adjust the size of the shadow, used when the modelelement is created. The details tab “Presentation” allows to set the shadow per modelelement, after they are created.

### 10.4.5.6. Modules Tab

This tab shows a list of modules that are installed, which may be enabled or disabled. Since this is a new concept for ArgoUML, it currently contains a list of modules that can not be removed, and a button to test the concept. Pressing this button adds a useless menu-item on the Tools menu, nothing else.

Notice also that this is a “new” modules concept so the old Pluggable modules do not work this way, and are not listed.

### 10.4.5.7. Extra Tabs added by Plugins

A plug-in module has the possibility to add extra tabs. One example is C++; it adds the following tab.

**Figure 10.18. The dialog for Settings - C++**.

---

### 10.5. The View Menu

This menu is used for actions that affect how the various panes are viewed.

#### 10.5.1. Goto Diagram...

This menu entry brings up a dialog box, describing all the diagrams in the current project under ArgoUML.

**Figure 10.19. The dialog for Goto Diagram...**

The dialog box contains a table with three columns and one row for each diagram in the current project.
A scroll bar gives access if the table is too long for the box. Double button 1 click on any row will select that diagram in the editing pane. The three columns are as follows.

- **Type.** Lists the type of diagram.
- **Name.** Lists the name given to the diagram.
- **Description.** Shows how many nodes and edges there are on the diagrams. A node is a “2-D” artifact and an edge is a connector artifact.

This dialog box is not modal, which allows it to remain open while editing the model for easy navigation.

**Warning**

The V0.22 implementation of ArgoUML does not immediately update the dialog box with changes made to diagrams: change of name, addition of diagrams, deletion of diagrams.

### 10.5.2. Find...

This menu entry brings up a non-modal dialog box for the ArgoUML search engine.

**Figure 10.20. The dialog for Find...**

At the top, the dialog box has four tabs labeled **Name and Location**, **Last Modified**, **Tagged Values** and **Constraints**. Of these all but the first are grayed out in the V0.22 version of ArgoUML (because they are not implemented yet), so the first tab is always selected.

The **Name and Location** specifies the search to be made. It contains the following:

- A text box labeled **Element Name:** specifies the name of the element (or artifact) to search for. Wild cards (*, ?) may be used here. A drop down gives access to find expressions previously used.
- A text box labeled **In Diagram:** specifies which diagrams are to be searched. Again wild cards may be used. Both these two text boxes have a default entry of *, i.e. match anything.
- To the right of these two text boxes, a selector labeled **Element Type:** allows you to specify the UML metaclass for which you are searching.
- A selector labeled **Find in:** allows the search to be made over the entire project (the default) or as a sub-search over the results of a previous search. When opened, a list of all the search result tabs appears.
- Beneath these boxes is the button **Clear Tabs.** This clears the display of tabs with the results from previous searches (see below). This button is downlighted if there are no tabs but the **Help** tab.
- And finally, there is the button **Find.** This causes the search specified in the text boxes and selectors above to be executed. The results are displayed in a tab taking up the lower two thirds of the page.

The lower two thirds of the dialog comprises an initial tab (labeled **Help**) giving summary help, and further tabs displaying the results of searches. These search tabs are labeled with a summary of the
search element in diagram and are divided horizontally in two halves.

Button 1 double clicking on these tabs removes the tab, and spawns a new window that contains the tab contents, i.e. the search results. This window can be moved and sized at will. This does not work for the help tab.

The top half is labeled **Search Results**: followed by a count of the number of items found. It comprises a table with one row for each element (artifact) and four columns. The width of the columns can be adjusted.

- **Type**: Lists the type of element (artifact).
- **Name**: Lists the name given to the element (artifact).
- **In Diagram**: Where the artifact is visible on a diagram, this lists the name of the diagram, otherwise it shows N/A.
- **Description**: Contains a description of the element (artifact). In ArgoUML V0.18 this seems to be restricted to the single entry docs.

Button 1 click on any row will give more information on that artifact by showing related artifacts in the bottom half (see below). Double click on any row describing an artifact on a diagram and that item and diagram will be selected.

The bottom half of the tab is a table labeled **Related Elements**: and is a table with the same columns as the top half. When an element (artifact) has been selected in the top half, this table shows the details of any related elements.

**Tip**

Enlarging the dialog vertically shows that the "Related Items" part changes in size, but not the Search results part. However, between them is a divider line and when hovering over this line, the mouse pointer changes into a sizing icon, and the border between these 2 areas can be moved up or down to redistribute the space in the window.

**Warning**

This dialog box is not modal, which allows it to remain open while editing the model for easy navigation. But the V0.22 implementation of ArgoUML does not immediately update the dialog box with changes made to the found artifacts: change of artifact name, change of diagram name. Deletion of a diagram does not stop the possibility to navigate to it.

### 10.5.3. Zoom

This entry brings up a sub-entry, which allows scaling the view of all diagrams to a factor of its normal size. This setting is not saved persistently.

The sub-menu items that can be selected are:

- **Zoom Out**: Shortcut (Ctrl-Minus). Gives more overview over the drawing.
- **Zoom Reset**: Returns to the default zoom ratio (i.e. 100%).
- **Zoom In**: Shortcut (Ctrl-Equals). Makes the items on the drawings bigger.
10.5.4. Adjust Grid

This cycles the grid representation on the screen through the following sequence:

- dots at 16 pixel spacing (the default);
- dots at 32 pixel spacing;
- no grid of any form;
- full grid at 16 pixel spacing; and
- full grid at 8 pixel spacing.

10.5.5. Adjust Grid Snap

This cycles the spacing of grid snapping through the following sequence:

- snap at 8 pixel spacing (the default);
- snap at 16 pixel spacing;
- snap at 32 pixel spacing; and
- snap at 4 pixel spacing.

**Note**

There is no option to turn off snap to grid altogether.

**Caution**

In the V0.22 version of ArgoUML this is not actually a true snap to grid. It just defines the increments by which artifacts are moved around. Thus if an item has an X coordinate of 4 and Grid Snap is set to 8, moving will take it to X coordinates of 12, 20, 28 etc, *not* 8, 16, 24 etc.

If you wish to align on true grid snap boundaries, you can use the `Ar- range > Align To Grid` menu (see Section 10.7.1, “Align”).

10.5.6. Page Breaks

This toggles whether page breaks are shown on the diagram (as white dotted lines).

**Warning**

This menu item does not work in ArgoUML V0.22.

10.6. The Create Menu
This menu provides for creating the various types of UML diagrams supported by ArgoUML.

10.6.1. New Use Case Diagram

This menu entry creates a blank use case diagram, and selects that diagram in the editing pane. If a package is currently selected, the use case diagram will be created within that package. This means that it will be shown within the package on the explorer hierarchy (under Package-centric view) and artifacts created on the diagram will be created within the namespace of the package. This does not only apply to a package, but also to a class, interface, use case, etc.

**Tip**

This does not prevent artifacts from other namespaces/packages appearing on the diagram. They can be added from the explorer using Add to Diagram from the button 2 pop-up menu.

10.6.2. New Class Diagram

This menu entry creates a blank class diagram, and selects that diagram in the editing pane. If a package is currently selected, the class diagram will be created within that package. This means that it will be shown within the package on the explorer hierarchy (under Package-centric view) and artifacts created on the diagram will be created within the namespace of the package. This does not only apply to a package, but also to a class, interface, use case, etc.

**Tip**

This does not prevent artifacts from other namespaces/packages appearing on the diagram. They can be added from the explorer using Add to Diagram from the button 2 pop-up menu.

10.6.3. New Sequence Diagram

This menu entry creates a blank sequence diagram, and selects that diagram in the editing pane. It also creates a Collaboration UML element, which is a container for the elements shown on the new diagram. If a class is currently selected, a sequence diagram and a collaboration will be created that represent the behaviour of that class. This means that the created elements will be shown within the class in the explorer hierarchy (under Package-centric view) and artifacts created on the diagram will be created within the namespace of the collaboration. A sequence diagram may not only represent the behavior of a class, but also of any other classifier, such as interface, use case, etc. It is also possible to make sequence diagrams for an operation.

10.6.4. New Collaboration Diagram

This menu entry creates a blank collaboration diagram, and selects that diagram. It also creates a Collaboration UML element, which is a container for the elements shown on the new diagram. If a package is selected when this menu item is activated, the collaboration diagram will be created within a collaboration within that package. This means that it will be shown within the collaboration within the package on the explorer hierarchy (under Package-centric view) and artifacts created on the diagram will be created within the namespace of the collaboration within the package.

**Tip**

This does not prevent artifacts from other namespaces/packages appearing on the diagram.
They can added from the explorer by dragging or by using Add to Diagram from the button 2 pop-up menu.

10.6.5. New Statechart Diagram

This menu entry creates a blank statechart diagram associated with the currently selected class, and selects that diagram in the editing pane. It also creates a Statemachine UML element, which is a container for the elements shown on the new diagram.

Statechart diagrams are associated with a model element capable of dynamic behavior, such as a classifier or a behavioral feature, which provides the context for the state machine it represents. Suitable model elements are e.g. a class, an operation, and a use case. If such element is not selected at the time the New Statechart Diagram menu is activated, then an unattached statemachine is created. To obtain a well-formed UML model, you have to set the context of the statemachine on its details pane.

10.6.6. New Activity Diagram

This menu entry creates a blank activity diagram associated with the currently selected class, and selects that diagram in the editing pane. It also creates a ActivityGraph UML element, which is a container for the elements shown on the new diagram.

Activity diagrams are associated with a model element capable of dynamic behavior, such as packages, classifiers (including use cases) and behavioral features. Suitable model elements are e.g. a class, a use case, an operation, and a package. If such element is not selected at the time the New Activity Diagram menu is activated, then an unattached ActivityGraph is created. To obtain a well-formed UML model, you have to set the context of the ActivityGraph on its details pane.

10.6.7. New Deployment Diagram

This menu entry creates a blank deployment diagram, and selects that diagram in the editing pane.

Tip

Artifacts from other namespaces/packages can be added from the explorer by dragging or by using Add to Diagram from the button 2 pop-up menu.

10.7. The Arrange Menu

This menu provides a range of functions to help in the alignment of artifacts on diagrams within the editing pane. In general the menu function invoked is applied to any artifact or artifacts currently selected in the editing pane.

10.7.1. Align

This sub-menu aligns the selected items. There are seven alignment options provided.

• Align Tops. Aligns the selected artifacts by their top edges.
• Align Bottoms. Aligns the selected artifacts by their bottom edges.
• Align Rights (Shortcut Ctrl-R). Aligns the selected artifacts by their right edges.
• **Align Lefts** (Shortcut Ctrl-L). Aligns the selected artifacts by their left edges.

• **Align Horizontal Centers**. Aligns the selected artifacts so their horizontal centers are in a vertical line.

• **Align Vertical Centers**. Aligns the selected artifacts so their vertical centers are in a horizontal line.

• **Align To Grid**. Aligns the selected artifacts so their top and right edges are on the grid snap boundary (see Section 10.5.5, “Adjust Grid Snap”) edge.

**Tip**

The alignment is to the current grid snap setting, which may be smaller, larger or the same as the displayed grid. Since items are aligned to the grid snap boundary any way when you place them, this menu entry has no effect unless you have either changed the grid snap to a larger value or used one of the other **Arrange** menu entries to push items off their initial positions.

### 10.7.2. Distribute

This sub-menu distributes the selected items. There are four distribution options provided.

• **Distribute Horizontal Spacing**. The leftmost and rightmost selected artifacts are not moved. The others are adjusted horizontally until the horizontal space (i.e. from the right edge of the left artifact to the left edge of the right artifact) is the same for all of the selected items.

• **Distribute Horizontal Centers**. The leftmost and rightmost selected artifacts are not moved. The others are adjusted horizontally until the distance between the horizontal centers of all the selected items is the same.

• **Distribute Vertical Spacing**. The top and bottom selected artifacts are not moved. The others are adjusted vertically until the vertical space (i.e. from the bottom edge of the top artifact to the top edge of the bottom artifact) is the same for all of the selected items.

• **Distribute Vertical Centers**. The top and bottom selected artifacts are not moved. The others are adjusted vertically until the distance between the vertical centers of all the selected items is the same.

### 10.7.3. Reorder

This sub-menu adjusts the ordering of overlapping items. There are four reorder options provided.

• **Forward**. The selected artifacts are moved one step forward in the ordering hierarchy with respect to other artifacts they overlap.

• **Backward**. The selected artifacts are moved one step back in the ordering hierarchy with respect to other artifacts they overlap.

• **To Front**. The selected artifacts are moved to the front of any other artifacts they overlap.

• **To Back**. The selected artifacts are moved to the back of any other artifacts they overlap.
10.7.4. Nudge

This sub-menu provides fine adjustment to the positioning of selected artifacts. There are four nudge options provided.

- Nudge Left. The selected artifacts are moved one pixel to the left.
- Nudge Right. The selected artifacts are moved one pixel to the right.
- Nudge Up. The selected artifacts are moved up one pixel.
- Nudge Down. The selected artifacts are moved up one pixel.

10.7.5. Set Preferred Size

This menu-item acts on all selected items on the current diagram. It resets all sizes of all artifacts to its "preferred" size, i.e. the minimum size for which all text fits inside.

10.7.6. Toggle Auto Resizing

This menu-item is a checkbox that currently does not do anything.

10.7.7. Layout

This menu-item provides an automatic diagram layout function, i.e. when activating this menu-item, all items on the current class diagram are rearranged according a certain layout algorithm.

This function currently only works for class diagrams. For all other types of diagrams, the menu-item is downlighted.

10.8. The Generation Menu

This menu provides support for code generation from UML diagrams. The functionality is built around the structural information of class diagrams.

Note

Without any plugin modules installed, ArgoUML supports only code generation of Java. ArgoUML V0.20 supports the following languages by plugin: C#, C++, php4, php5.

Warning

Code generation is still very much a work in progress. The current version of ArgoUML will generate a structural template for your code, but is not able to handle behavioral specifications to generate code for the dynamic behavior of the model.

10.8.1. Generate Selected Classes ...

This menu entry brings up a dialog box for the ArgoUML code generator (see Figure 10.21, "The dialog for Generate Selected Classes....").
10.8.2. Generate All Classes...

Shortcut F7.

This function behaves as Generate Selected Classes... (see Section 10.8.1, “Generate Selected Classes ...”) would with all classes in the current diagram selected.

10.8.3. Generate Code for Project... (To be Written)

10.8.4. Settings for Generate for Project... (To be Written)

10.9. The Critique Menu

This menu controls one of ArgoUML’s unique features—the use of critics to guide the designer. The theory behind this is well described in Jason Robbins’ PhD dissertation [http://argouml.tigris.org/docs/robbins_dissertation/].

Note

A word about terminology: The critics are background processes, which evaluate the current model according to various “good” design criteria. There is one critic for every design criterion.

The output of a critic is a critique—a statement about some aspect of the model that does not appear to follow good design practice.

Finally a critique will generally suggest how the bad design issue it has identified can be rectified, by raising a to-do item.

Note
The critics run as asynchronous processes in parallel with the main ArgoUML tool. Changes typically take a second or two to propagate as the critics wake up.

10.9.1. Toggle Auto-Critique

This is a check box, controlling whether the critics are running. By default it is checked. If unchecked, then all critics are disabled, and any to-do items generated by critics (the only others being those the designer has added by hand) are hidden in the to-do pane.

10.9.2. Design Issues...

This menu entry brings up a dialog box controlling how critics associated with a particular design area are to be handled (see Figure 10.22, “The dialog for Design Issues...”).

Figure 10.22. The dialog for Design Issues...

ArgoUML categorizes critics according to the design issue they address. There are 16 such categories. The critics in each category are discussed in detail in the chapter on critics (Chapter 15, The Critics).

The sliders may be set for each category to control the critics that trigger for that category. Setting a slider to Off will disable all critics in that category, and remove all associated to-do items from the to-do pane.

Setting a slider to a higher priority value will enable all critics at or above that priority level within the design issue category (Off being the lowest priority).

Note

The sliders are set by default to High for all design categories.

10.9.3. Design Goals...

This menu entry brings up a dialog box controlling how design goals are to be handled (see Figure 10.23, “The dialog for Design Goals...”).

Figure 10.23. The dialog for Design Goals...

ArgoUML has the concept that the designer will have a number of design goals to be achieved (for example good structural representation, detailed behavioral representation etc). Critics are associated with one or more goals.

This dialog allows the user to specify the priority of each design goal.

The sliders may be set for each design goal to control the critics that trigger for that goal. Setting a slider to zero will disable all critics in that goal, and remove all associated to-do items from the to-do pane.

Setting a slider to a higher value will enable all critics at or above that priority level within the design issue category (1 being the highest priority and 5 the lowest).
Tip
It may be useful to think of this function as very similar to Design Issues... (see Section 10.9.2, “Design Issues...”), but with grouping of critics according to the outcomes of OOA&D rather than grouping according to the structure of UML.

Warning
The V0.20 version of ArgoUML provides a single design goal, Unspecified, with its slider set by default to priority 1. However it contains no critics and so has no effect.

10.9.4. Browse Critics...
This menu entry brings up a dialog box controlling the individual critics (see Figure 10.24, “The dialog for Browse Critics...”).

Figure 10.24. The dialog for Browse Critics....

This dialog controls the behavior of individual critics. To the left is a list of all the critics, to enable them to be switched on or off individually. For each critic there are three columns, labeled Active, Headline and Snoozed. The first of these is a check box, which may be toggled with button 1 click. The second is the headline name of the critic, the third indicates if the critic has been snoozed from the to-do pane (see Chapter 14, The To-Do Pane. A critic is only really active if the box in the first column is checked and the critic has not been snoozed.

Any critic for which the box in the first column is unchecked is inactive and will not trigger. In addition any to-do items associated with that critic will be removed from the to-do pane.

The V0.20 version of ArgoUML has a total of 90 critics, a few of which are incompletely implemented. They are described in detail by design issue category in the chapter on critics (see Chapter 15, The Critics).

To the right of the list are a series of fields, titled Critic Details, giving detailed control over individual critics. Selecting a critic in the list on the left will populate the fields for that critic.

The first field on the right is titled Critic Class: and then the full name of the class in ArgoUML that implements the critic. This name can be used as unique identifier of the critique, e.g. in conversations about the critic.

The first field below this title is a text box labeled Headline: giving the complete headline of the critic (which may be truncated in the list on the left).

Note
In the headline you may see the text <ocl>self</ocl>, which will be replaced by the name of the artifact in question when the critic is triggered.

The next field is a drop-down selector, labeled Priority:. The three options available are High, Medium and Low and specify the priority category of any to-do item generated by this critic. This does not alter the priority of the already existing todo items, only the newly generated ones. Changing the priority of a critic is not saved persistently.
The next field is labeled MoreInfo: and contains a URL pointing to further information with a button to the right labeled Go to navigate to that URL.

**Warning**

In the V0.20 release of ArgoUML there is no further information available, and the Go button is always grayed out and disabled.

The next field is labeled Description: and is a text area with a detailed explanation of what this critic means. If the text is too large for the area a scroll bar is provided to the right.

**Note**

In this text area you may see the text `<ocl>self</ocl>`, which will be replaced by the name of the artifact in question when the critic is triggered.

The last field is a drop-down selector labeled Use Clarifier, with three options, Always, If Only One and Never.

Clarifiers are the icons and wavy red underlines drawn on the actual diagrams to indicate the artefact to which the critic refers. The original intention was to make the mapping from critics to clarifiers somewhat customizable.

For example one user might make a Missing Name critic show a red underline, another user might turn off the clarifier, or have it draw a wavy green underline or a blue questionmark. Critics with their clarifier's disabled would still produce feedback that is listed in the to-do pane.

**Caution**

In the V0.20 release of ArgoUML this selector has no function whatsoever. It is for future development.

Underneath the fields are three buttons in a horizontal row.

- **Wake.** It is possible to snooze a critic from the to-do pane (see Chapter 14, The To-Do Pane), which makes the critic inactive for a period. If the critic has been snoozed, this button is enabled and will wake the critic back up again. Otherwise it is grayed out.

  **Tip**

  You can tell a snoozed critic, because in the list on the left it will be indicated in the third column.

- **Configure.** This button is for configuring the critic.

  **Caution**

  In the V0.20 version of ArgoUML this function is not implemented, and this button is always grayed out. It is for future development.

- **Edit Network.** Right now critics are implemented in java code. That means end-users cannot add new critics.
The idea of a critic network is that they would be a state machine like diagram with several steps. Each step would express a condition which, collectively with the other steps associated with that critic, articulates the “rule” that the critic is providing. If the rule fires, then remaining steps would define the steps of the wizard to help the user fix the problem.

The ideas behind this are discussed in Chapter 4 of Jason Robbins PhD dissertation (http://argouml.tigris.org/docs/robbins_dissertation/diss4.html. In particular look at Figure 1-6 in this chapter and the related discussion.

A suggested implementation is that the conditions could be written in OCL against the UML metamodel. A library of predefined conditions and steps would allow end-users to build new critics by combining those in novel ways.

**Caution**

In the V0.20 version of ArgoUML this function is not implemented, and this button is always grayed out. It is for future development.

Finally the bottom right of the dialog contains a button labeled OK. Button 1 click here dismisses the dialog.

### 10.10. The Tools Menu

This menu provides a generic menu attachment point for any plug-ins provided with ArgoUML. The standard system has no plug-in, and this menu entry is empty by default.

### 10.11. The Help Menu

This menu provides help on the use of ArgoUML. It has two entries.

#### 10.11.1. System Information

This menu entry brings up the system information dialog, see Figure 10.25, “The dialog for System Information.”

**Figure 10.25. The dialog for System Information.**

Use this menu to describe the system that runs ArgoUML to the system manager or developer. Pressing the button Run Garbage Collector not only runs the Java gargeage collector, but also refreshes the information shown. To facilitate copy and paste into (e.g.) an email, the button Copy Information to System Clipboard is foreseen. The Cancel button dismisses the dialog box.

#### 10.11.2. About ArgoUML

This menu entry brings up the help window for ArgoUML (see Figure 10.26, “The help window for ArgoUML”).

**Figure 10.26. The help window for ArgoUML**
The window has six tabs, which are selected by button 1 click. By default the first tab (Splash) is shown.

- **Splash.** This displays the picture shown when ArgoUML starts up, and the current version number.
- **Version.** This provides version information on the various packages that make up ArgoUML, and some operating system and environment information.
- **Credits.** This details all those who have created ArgoUML, including contact details for the various module owners.
- **Contact Info.** This gives the major contact points for the ArgoUML project—the web site, and the developers mailing list.
- **Report bugs.** This gives information about how to deal with bugs in ArgoUML. It is important that all bugs are reported, and all cooperation is appreciated.
- **Legal.** A statement of the FreeBSD license which covers all the ArgoUML software.

**Caution**

The various documentation of the project are not all covered by FreeBSD (which is really meant for software). In particular this manual is covered by the OpenPub license (see Appendix F, *Open Publication License*).
Chapter 11. The Explorer

The Explorer was previously called Navigation Pane/Tree or sometimes Navigator Pane/Tree.

11.1. Introduction

Figure 11.1, “Overview of the explorer” shows the ArgoUML window, with the explorer highlighted.

Figure 11.1. Overview of the explorer

The explorer allows the user to view the structure of the model from a number of predefined perspectives. It also allows the user to define their own perspectives for custom exploring of the model.

An important feature, related to the cognitive psychology ideas behind ArgoUML is that not all artifacts are necessarily shown in all perspectives. Rather, the perspectives are used to implement hiding of uninteresting parts of the model.

11.2. Mouse Behavior in the Explorer

Behavior of the mouse in general, and the naming of the buttons is covered in the chapter on the overall user interface (see Chapter 8, Introduction).

11.2.1. Button 1 Click

Within the hierarchical display, elements which have sub-hierarchies are indicated by when the hierarchy is hidden and when the hierarchy is open.

Button 1 click over the name of any diagram artifact will cause the diagram to be selected and displayed in the editing pane. Its details will also be displayed in the details pane.

Button 1 click over the name of any artifact other than a diagram in the main area of the explorer will cause it to be selected, and its details shown in the details pane. If the artifact is part of a diagram currently displayed in the editing pane, it will be highlighted there.

Note

If the artifact is part of a diagram other than that currently displayed in the Editing Pane, there will be no change of diagram in the Editing Pane.

Where button 2 click has been used to bring up a context sensitive pop-up menu (see below), button 1 click is used to select the menu entry required. button 1 click outside the menu area will remove it.

11.2.2. Button 1 Double Click

This has the effect of a button 1 single click, and if the tree item was not a leaf, it will toggle the hierarchy open or close.

11.2.3. Button 1 Motion
Button 1 motion means that you pick up one or more modelelements, and drag them to a new location. Dropping the modelelement somewhere causes ArgoUML to execute some function that depends on where you drop the modelelements.

### 11.2.3.1. From Explorer to Explorer

Releasing the mouse button above a namespace, makes the modelelement owned by the namespace. In the Package-centric explorer perspective, this means a straight-forward drag-and-drop function.

Use this drap and drop feature to easily move e.g. classes from one package into another.

### 11.2.3.2. From Explorer to Diagram

Dropping a modelelement on the diagram is the equivalent of the "Add to Diagram" function. Hence, if the diagram did not yet show this modelelement, it is added.

Use this drap and drop feature e.g. to easily create a diagram from imported XMI files. This because XMI files contain all the modelelements, but not any diagram information.

### 11.2.4. Button 2 Actions

When used in the the explorer, this will display a selection dependent pop-up menu. Menu entries are highlighted (but not selected) and sub-menus exposed by subsequent mouse motion (without any buttons). Menu entry selection is with button 1 or button 2.

### 11.2.5. Button 2 Double Click

This has no effect other than that of button 2 single click.

### 11.3. Keyboard Behavior in the Explorer

All keys active in a tree widget have their normal behaviour.

When a diagram is selected, pressing Ctrl-C will copy the diagram in GIF format to the system clipboard.

### 11.4. Perspective Selection

The artifacts in the ArgoUML model may be configured for displaying in the tree by a number of perspectives. To this end, a drop-down at the top allows selection of the explorer perspective.

Below that, there is a drop-down to select the ordering of the artifacts within the hierarchy. The two possibilities are "Order by Type, Name" and "Order by Name". The former groups all items per type, and sorts them per group alphabetically on the name. The latter simply sorts on name only.

The following explorer perspectives may be selected in the drop-down at the top:

- **Package-centric** (the default). The exploring hierarchy is organized by package hierarchy. The top level shows the model. Under this are all the top level packages in the model and all the artifacts that are directly in the namespace of the model.

  Beneath each package are all the artifacts that sit within the namespace of that package, including any further sub-packages (which in turn have their own sub-hierarchies).
• **Class-centric.** Shows classes in their package hierarchy as well as datatypes and use case diagram elements. Similar to the Package-centric view but it doesn’t show connecting or associating elements.

• **Diagram-centric.** In this view the top level comprises all the diagrams in the model. Beneath each diagram is a flat listing of all the artifacts on the diagram. Artifacts that have sub-artifacts that do not appear on the diagram have their own hierarchy (for example attributes and operations of classes).

• **Inheritance-centric.** In this view the top level shows the model. Beneath this are all artifacts that have no generalization in the model. Those artifacts that have specializations have a sub-hierarchy showing the specializations.

• **Class Associations.** In this view the top level shows the model. Beneath this are all diagrams and all classes. All classes that have associations have a hierarchy tracking through the associated classes.

• **Residence-centric.** In this view the model is shown at the top-level, with below it only Nodes, and below these only components that reside on the nodes, and below these components all elements that reside on the components.

• **State-centric.** In this view the top level shows all the state machines and all activity graphics associated with classes.

  Beneath each state machine is a hierarchy showing the statechart diagram and all of the states. Beneath each state is a list of the transitions in and out of the state.

  Beneath each activity graph is a hierarchy showing the activity diagram and all of the action states. Beneath each action state is a list of the transitions in and out of the action state.

• **Transitions-centric.** This is very similar to State-centric view, but under each state machine is listed the diagrams and all transitions on the diagram, with states being shown as sub-hierarchies under their connected transitions.

  Similarly under each activity graph is listed the diagrams and all transitions on the diagram, with action states being shown as sub-hierarchies under their connected transitions.

• **Composition-centric.** In this view, all modelelements are shown according their composition in the UML metamodel.

  This perspective shows far more modelelements then all others - it does not hide anything. Hence, this view is not so user-friendly, but very suited for the UML specialist.

### 11.5. Configuring Perspectives

The explorer is designed to be user configurable, to allow the designer to view in his or her preferred way.

#### 11.5.1. The Configure Perspectives dialog

button 1 click on the "Configure Perspectives" icon ( ) at the top left of the explorer brings up the explorer perspectives dialog (see Figure 11.2, “The Configure Perspectives dialog box”).

**Figure 11.2. The Configure Perspectives dialog box**
The top half of the dialog contains a list of all the currently defined perspectives and to the right a series of buttons stacked vertically. Button 1 click can be used to select a perspective. You can select only one perspective at a time.

Selecting a perspective reveals a text field above the list, where the name of the perspective can be edited.

The lower half of the dialog contains two list areas. The one on the left, labeled Rules Library, contains the list of available rules that may be used to create the perspective. The one on the right, labeled Selected Rules contains the actual rules chosen for the perspective that has been selected in the list of perspectives at the top. In both lists, you can select only one rule at a time.

Separating the two areas in the lower half of the dialog are buttons labeled >> and <<. The first of these transfers the rule selected in the library on the left to the list of rules on the right i.e. it adds a rule to the perspective. The second one transfers the rule selected on the right to the library list on the left i.e. it removes a rule from the perspective.

If you hover the mouse over the horizontal line that separates the two halves of the dialog, then you see it change shape, to indicate that you can grab this line and drag it up or down.

All three titles of the lists show the number of items in the list. ArgoUML V0.20 has 8 default perspectives, and 68 rules in the library to build perspectives from.

The buttons at the top right are explained as follows:

- **New.** This creates a new perspective from scratch with no rules selected, with an automatically generated name.
- **Remove.** This removes the selected perspective.
- **Duplicate.** This creates a copy the selected perspective so it can be used as the basis of a new perspective. The new one is named "Copy of" followed by the original name.
- **Move Up.** This moves the selected perspective one place up in the list. This button is downlighted for the topmost perspective.
- **Move Down.** This moves the selected perspective one place down in the list. This button is downlighted for the last perspective.
- **Restore Defaults.** This restores all perspectives and their selected rules to the build-in defaults of ArgoUML.

At the very bottom right is a button labeled OK to be used when all changes are complete. Button 1 click on this button will close the dialog window. The changes are saved when you exit ArgoUML (or immediately by activating the menuitem File->Save Configuration) in the argo.user.properties file.

Then there is the Cancel button, which cancels all changes made in the dialog. Pressing the dialog close icon (usually at the top right corner) has the same effect as pressing the cancel button.

## 11.6. Context Sensitive Menu

Button 2 Click over any selected artifact in the main area of the explorer will cause a pop-up menu to appear.

### 11.6.1. Add to Diagram
This entry on the pop-up menu appears for any artifact that could be added to the diagram in the editing pane.

The item can be placed in a diagram by moving the cursor to the editing pane or a spawned editing pane window (where it will appear as a cross) and clicking button 1.

Caution

This menu entry only appears as not grayed out, if the diagram in the editor pane allows to contain the artifact, and the artifact is not present yet in the diagram. ArgoUML will not let you place more than one copy of any particular artifact on a diagram.

11.6.2. Delete From Model

This entry on the pop-up menu appears for any artifact that could be deleted from the model.

Warning

This deletes the artifact from the model completely, not just from the diagram. To remove the artifact just from the diagram, use the edit menu (see Section 10.4.2, “Remove From Diagram”).

Caution

You can delete a diagram from the model. Depending on the type of diagram, that might delete all artifacts shown on the diagram. To illustrate the differences, consider the following examples:

• Deleting a class diagram does not delete any artifact drawn on it. All artifacts that were shown on the diagram remain present in the model. This because a class diagram does not "map" on any artifact according the UML standard V1.4.

• Deleting a statechart diagram also deletes the statemachine it represents, and hence also all the artifacts owned by the statemachine. This because a statechart diagram does "map" into a StateMachine according the UML standard V1.4.

11.6.3. Set Source Path... (To be written)

This entry on the pop-up menu ...

11.6.4. Add Package

This entry on the pop-up menu is available whenever an artifact is selected that may contain a package, e.g. a package. After activating this menu the artifact will own a new package.

11.6.5. Add All Classes in Namespace

This entry on the pop-up menu is available for Class Diagrams only. Activating this menu-item will add all classes in the current namespace to the diagram. They will be located at the top left corner?obviously a perfect occasion to use the "Arrange->Layout" function in the menu.
Chapter 12. The Editing Pane

12.1. Introduction

Figure 12.1, “Overview of the editing pane” shows the ArgoUML window with the editing pane highlighted.

Figure 12.1. Overview of the editing pane

This is where all the diagrams are drawn. In earlier versions of ArgoUML, this pane went under a variety of names. You may encounter “drawing pane”, “diagram pane” or “multi-editor pane” in other documentation that is still being updated.

The pane has a tool bar at the top, and a single tab labeled As Diagram at the bottom, which has no function in the 0.20 version of ArgoUML. The main area shows the currently selected diagram, of which the name is shown in the window title bar.

12.2. Mouse Behavior in the Editing Pane

Behavior of the mouse in general, and the naming of the buttons is covered in the chapter on the overall user interface (see Chapter 8, Introduction).

12.2.1. Button 1 Click

In the tool bar of the editing pane, button 1 click is used to select a tool for creating a new artifact and adding it to the diagram (see double clicking for creating multiple artifacts). For most tools, adding a new artifact to the diagram is achieved by moving the mouse into the editing area and clicking again.

In the main editing area button 1 click is used to select an individual artifact.

Many artifacts (e.g. actor, class) show special handles when selected and the mouse hovers over them. These are called “Selection Action Buttons”, see Section 12.5, “Selection Action Buttons”. They appear at the sides, top and bottom, and indicate a relationship type. Clicking on a Selection Action Button creates a new related artifact, with the relation of the type that was indicated. If the shift key is pressed when hovering the mouse over a selected artifact, sometimes different handles are shown, which stand for different relation types.

Where button 2 click has been used to bring up a context sensitive pop-up menu (see below), button 1 click is used to select the menu entry required. The pop-up menu will be removed by any button 1 click outside of the menu area.

There are various more detailed effects, which are discussed under the descriptions of the various tools (see Section 12.3, “The tool bar”).

12.2.2. Button 1 Double Click

When used on the tool bar with a tool to add an artifact, the selected artifact will be added multiple times to the drawing area, once for each further button click, until the tool is again selected or another tool chosen.

When used within the drawing area on an artifact that has sub-components, double click will select the
For example, double clicking over an operation compartment of a class will select the operation. Or create one if there is none yet.

A special use is with package artifacts on the class diagram. A double click on a package will navigate to the class diagram associated with a package (the first created if there is more than one), or will offer to create one for you if there is none. See Figure 12.2, “The dialog for adding a new class diagram”

**Figure 12.2. The dialog for adding a new class diagram**

### 12.2.3. Button 1 Motion

Where the artifact being added is some form of connector its termination point is shown with button 1 up over the terminating artifact. button 1 click may be used in the space between artifacts to create articulation points in the connector. This is particularly useful where connectors must loopback on themselves.

Over graphical artifacts button 1 motion will move the artifact to a new position.

Graphical artifacts that are selected show handles at the corners or ends, and these can be used for resizing.

Some artifacts (e.g. actor, class) show special handles (called “Selection Action Buttons”, see Section 12.5, “Selection Action Buttons”) at the sides, top and bottom, which can be dragged to form types of relationship with other artifacts.

Where the artifact is some form of connector between other items, button 1 motion other than at a handle will cause a new handle to be created, allowing the connector to be articulated at that point. This only works when the connecting line is not straight angled. Such new handles can be removed by moving them to the end of the connector.

There are various more detailed effects, which are discussed under the descriptions of the various tools (see Section 12.3, “The tool bar”).

### 12.2.4. Shift and Ctrl modifiers with Button 1

Where multiple selections are to be made, the CTRL key is used with button 1 to add unselected artifacts to the current selection. Where an artifact is already selected, it is removed from the current selection.

Clicking Button 1 while the SHIFT key is pressed invokes the broom tool, which causes the selected artifacts (and any others swept up with them) to be moved with the broom tool (see Section 12.3.1, “Layout Tools”).

### 12.2.5. Alt with Button 1 motion

Button 1 down anywhere in the diagram while the ALT key is pressed, allows to scroll the canvas in all directions with button 1 motion.

### 12.2.6. Button 2 Actions

When used over artifacts in the editing pane, this will display a context dependent pop-up menu.
Menu entries are highlighted (but not selected) and sub-menus exposed by subsequent mouse motion (without any buttons). Menu entry selection is with button 1 or button 2. See Section 12.9, “Pop-Up Menus” for details of the specific pop-up menus.

In case multiple elements are selected, the pop-up menu only appears if all the items are of the same kind. In this case, the functions apply to all selected elements.

12.2.7. Button 2 Double Click

This has no effect other than that of button 2 single click.

12.2.8. Button 2 Motion

This is used to select items in a context sensitive menu popped up by use of button 2 click.

12.3. The tool bar

The toolbar at the top of the editing pane provides the main functions of the pane. The default tool is the Select tool (). In general button 1 click on any tool selects a tool for one use, before reverting to the default tool, and button 1 double click selects a tool for repeated use.

The tools fall into four categories.

- Layout tools. Provide assistance in laying out artifacts on the diagram.
- Annotation tools. Used to annotate artifacts on the diagram.
- Drawing tools. Used to add general graphic artifacts to diagrams.
- Diagram specific tools. Used to add UML artifacts specific to a particular diagram type to the diagram.

Some of the tools that are generally not all used so often, are combined in a dropdown, to take less space on the toolbar. See e.g. Figure 12.3, “The drawing tools selector.”. Press the symbol at the right of the tool to pop it open. These drop-down tools remember their last used tool persistently. This means that when ArgoUML starts, they show the last tool that was activated the previous time ArgoUML was run.

12.3.1. Layout Tools

The following two tools are provided in all diagrams in this category.

- Select. This tool provides for general selection of artifacts on the diagram. Button 1 click will select an artifact. CTRL with button 1 can be used to select (or deselect) multiple artifacts. Button 1 motion will move selected 2D items or add and move a new control point on a link. Button 1 motion on a selected component's control point will stretch that component's shape.
- Broom. Button 1 motion with this tool provide a “broom” which will sweep all artifacts along. This is a very shortcut way of lining things up.

The Broom can also be invoked by using SHIFT with button 1 motion when the Select tool is in use.

The Broom is discussed at length in its own chapter, see Section 12.4, “The Broom”
Tip

Additional control of artifact layout is provided through the Arrange menu (see Section 10.7, “The Arrange Menu”).

12.3.2. Annotation Tools

The annotation tool Comment () is used to add a comment to a selected UML artifact.

Caution

Unlike most other tools you use the Select tool to select an artifact, and then button 1 click on Comment to create the comment. If no element is selected when the comment tool is clicked, then the comment is created and put at the left top corner.

The comment is created alongside the selected artifact, empty by default. The text can be selected with button 1 double-click and edited from the keyboard.

The UML standard allows comments to be attached to any artifact.

You can link any comment to additional elements using the CommentLink () tool.

12.3.3. Drawing Tools

These are a series of tools for providing graphical additions to diagrams. Although they are not UML artifacts, the UML standard provides for such decoration to improve the readability of diagrams.

Tip

These drawing tools provide a useful way to partially support some of the UML features (such as general purpose notes) that are missing from the current release of ArgoUML.

Eight tools are provided, all grouped into one drop-down widget. See Figure 12.3, “The drawing tools selector.”. Button 1 click on the diagram will place an instance of the graphical item of the same size as the last one placed. The size can be controlled by button 1 motion during placement. One side or end of the element will be at button 1 down, the other side or end at button 1 up. In general after they are placed on the diagram, graphical elements can be dragged with the Select tool and button 1 and re-sized by button 1 motion on the handles after they have been selected.

Figure 12.3. The drawing tools selector.

- **Rectangle.** Provides a rectangle.
- **Rounded Rectangle.** Provides a rectangle with rounded corners. There is no control over the degree of rounding.
- **Circle.** Provides a circle.
- **Line.** Provides a line.
• Text. Provides a text box. The text is entered by selecting the box and typing. Text is centered horizontally and after typing, the box will shrink to the size of the text. However it can be re-sized by dragging on the corners.

• Polygon. Provides a polygon. The points of the polygon are selected by button 1 click and the polygon closed with button 1 double click (which will link the final point to the first point).

• Spline. Provide an open spline. The control points of the spline are selected with button 1 and the last point selected with button 1 double click.

• Ink. Provide a polyline. The points are provided by button 1 motion.

12.3.4. Use Case Diagram Specific Tools

Several tools are provided specific to UML artifacts on use case diagrams. The detailed properties of these artifacts are described in the section on use case diagram artifacts (see Chapter 17, Use Case Diagram Artifact Reference).

• Actor. Add an actor to the diagram. For convenience, when the mouse is over a selected actor it displays two handles to left and right which may be dragged to form association relationships.

• Use Case. Add a use case to the diagram. For convenience, when the mouse is over a selected use case it displays two handles to left and right which may be dragged to form association relationships and two handles top and bottom which may be dragged to form generalization and specialization relationships respectively.

• Association. Add an association between two artifacts selected using button 1 motion (from the first artifact to the second). There are 6 types of association offered here, see Figure 12.4, “The association tool selector.”: association, aggregation and composition, and all these three can be bidirectional or unidirectional.

Figure 12.4. The association tool selector.

• Dependency. Add a dependency between two artifacts selected using button 1 motion (from the dependent artifact).

• Generalization. Add a generalization between two artifacts selected using button 1 motion (from the child to the parent).

• Extend. Add an extend relationship between two artifacts selected using button 1 motion (from the extended to the extending use case).

• Include. Add an include relationship between two artifacts selected using button 1 motion (from the including to the included use case).

• Add Extension Point. Add an extension point to a selected use case. The extension point is given the default name newEP and location loc. Where the extension point compartment is displayed, the extension point may be edited by button 1 double click and using the keyboard, or by selecting with button 1 click (after the use case has been selected) and using the property tab. Otherwise it may be edited through its property tab, selected through the property tab of the owning use case.

Note
12.3.5. Class Diagram Specific Tools

Several tools are provided specific to UML artifacts on class diagrams. The detailed properties of these artifacts are described in the section on class diagram artifacts (see Chapter 18, Class Diagram Artifact Reference).

- **Package.** Add a package to the diagram.
- **Class.** Add a class to the diagram. For convenience, when the mouse is over a selected class it displays two handles to left and right which may be clicked or dragged to form association relationships (or composition in case SHIFT has been pressed) and two handles top and bottom which may be dragged or clicked to form generalization and specialization relationships respectively.
- **Association.** Add an association between two artifacts selected using button 1 motion (from the first artifact to the second). There are 2 types of association offered here, bidirectional or unidirectional.
- **Composition.** Add an composition between two artifacts selected using button 1 motion (from the first artifact to the second). There are 2 types of composition offered here, bidirectional or unidirectional.
- **Aggregation.** Add an aggregation between two artifacts selected using button 1 motion (from the first artifact to the second). There are 2 types of aggregation offered here, bidirectional or unidirectional.
- **Generalization.** Add a generalization between two artifacts selected using button 1 (from the child to the parent).
- **Interface.** Add an interface to the diagram. For convenience, when the mouse is over a selected interface it displays a handle at the bottom which may be dragged to form a realization relationship (the target being the realizing class).
- **Realization.** Add a realization between a class and an interface selected using button 1 motion (from the realizing class to the realized interface).
- **Dependency.** Add a dependency between two artifacts selected using button 1 motion (from the dependent artifact). There are also 2 special types of dependency offered here, Permission () and Usage (). A Permission is created by default with stereotype Import, and is used to import elements from one package into another.
- **Attribute.** Add a new attribute to the currently selected class. The attribute is given the default name newAttr of type int and may be edited by button 1 double click and using the keyboard, or by selecting with button 1 click (after the class has been selected) and using the property tab.

**Note**

This tool is grayed out except when a class is selected.

- **Operation.** Add a new operation to the currently selected class or interface. The operation is given the default name newOperation with no arguments and return type void and may be edited by
button 1 double click and using the keyboard, or by selecting with button 1 click (after the class has been selected) and using the property tab.

Note

This tool is grayed out except when a class or interface is selected.

- **Association Class.** Add a new association class between two artifacts selected using button 1 motion (from the first artifact to the second).

- **Datatype.** Add a datatype to the diagram. For convenience, when the mouse is over a selected datatype it displays handles at the top and at the bottom which may be clicked or dragged to form a generalization relationship (the target being another datatype). There are 2 other elements available here, Enumeration and Stereotype. These two have similar handles, except the one at the top of a stereotype: when clicked, it creates a metaclass, connected by a dependency marked with ??stereotype?? This eases the creation of "stereotype declaration" diagrams - see the literature on the subject.

### 12.3.6. Sequence Diagram Specific Tools

Seven tools are provided specific to UML artifacts on sequence diagrams. The detailed properties of these artifacts are described in the section on sequence diagram artifacts (see Chapter 19, *Sequence Diagram Artifact Reference*).

- **ClassifierRole.** Add a classifierrole to the diagram.

- **Message with Call Action.** Add a call message between two classifierroles selected using button 1 motion (from the originating classifierrole to the receiving classifierrole).

- **Message with Return Action.** Add a return message between two classifierroles selected using button 1 motion (from the originating classifierrole to the receiving classifierrole).

- **Message with Create Action.** Add a create message between two classifierroles selected using button 1 motion (from the originating classifierrole to the receiving classifierrole).

- **Message with Destroy Action.** Add a destroy message between two classifierroles selected using button 1 motion (from the originating classifierrole to the receiving classifierrole).

- **Add Vertical Space to Diagram.** Add vertical space to a diagram by moving all messages below this down. Click the mouse at the point where you want the space to be added and drag down the screen vertically the distance which matches the height of the space you’d like to have added.

- **Remove Vertical Space in Diagram.** Remove vertical space from diagram and move all elements below up vertically. Click and drag the mouse vertically over the space that you want deleted.

### 12.3.7. Collaboration Diagram Specific Tools

Three tools are provided specific to UML artifacts on collaboration diagrams. The detailed properties of these artifacts are described in the section on collaboration diagram artifacts (see Chapter 21, *Collaboration Diagram Artifact Reference*).
• **Classifier Role.** Add a classifier role to the diagram.

• **Association Role.** Add an association role between two classifier roles selected using button 1 motion (from the originating classifier role to the receiving classifier role). There are 6 types of association roles offered here, see Figure 12.4, “The association tool selector.”: association, aggregation and composition, and all these three can be bidirectional or unidirectional.

• **Generalization.** Add a generalization between two artifacts selected using button 1 (from the child to the parent).

• **Dependency.** Add a dependency between two artifacts selected using button 1 motion (from the dependent artifact).

• **Add Message.** Add a message to the selected association role.

  **Note**
  This tool is grayed out except when an association role is selected.

### 12.3.8. Statechart Diagram Specific Tools

Eleven tools are provided specific to UML artifacts on statechart diagrams. The detailed properties of these artifacts are described in the section on statechart diagram artifacts (see Chapter 20, *Statechart Diagram Artifact Reference*).

• **Simple State.** Add a simple state to the diagram.

• **Composite State.** Add a composite state to the diagram. All artifacts that are subsequently placed on the diagram on top of the composite state will form part of that composite state.

• **Transition.** Add a transition between two states selected using button 1 motion (from the originating state to the receiving state).

• **Synch State.** Add a synchstate to the diagram.

• **Submachine State.** Add a submachinestate to the diagram.

• **Stub State.** Add a stubstate to the diagram.

• **Initial.** Add an initial pseudostate to the diagram.

  **Caution**
  There is nothing to stop you adding more than one initial state to a diagram or composite state. However to do so is meaningless, and one of the critics will complain.

• **Final State.** Add a final state to the diagram.

• **Junction.** Add a junction pseudostate to the diagram.

  **Caution**
  A well formed junction should have at least one incoming transition and exactly one
outgoing. ArgoUML does not enforce this, but an ArgoUML critic will complain about any junction that does not follow this rule.

• **Choice.** Add a choice pseudostate to the diagram.

  **Caution**

  A well formed choice should have at least one incoming transition and exactly one outgoing. ArgoUML does not enforce this, but an ArgoUML critic will complain about any choice that does not follow this rule.

• **Fork.** Add a fork pseudostate to the diagram.

  **Caution**

  A well formed fork should have one incoming transition and two or more outgoing. ArgoUML does not enforce this, but an ArgoUML critic will complain about any fork that does not follow this rule.

• **Join.** Add a join pseudostate to the diagram.

  **Caution**

  A well formed join should have one outgoing transition and two or more incoming. ArgoUML does not enforce this, but an ArgoUML critic will complain about any join that does not follow this rule.

• **Shallow History.** Add a shallow history pseudostate to the diagram.

• **Deep History.** Add a deep history pseudostate to the diagram.

### 12.3.9. Activity Diagram Specific Tools

Seven tools are provided specific to UML artifacts on activity diagrams. The detailed properties of these artifacts are described in the section on activity diagram artifacts (see Chapter 22, *Activity Diagram Artifact Reference*).

• **Action State.** Add an action state to the diagram.

• **Transition.** Add a transition between two action states selected using button 1 motion (from the originating action state to the receiving action state).

• **Initial.** Add an initial pseudostate to the diagram.

  **Caution**

  There is nothing to stop you adding more than one initial state to a diagram. However to do so is meaningless, and one of the critics will complain.
• **Final State.** Add a final state to the diagram.

• **Junction.** Add a junction (decision) pseudostate to the diagram.

  **Caution**

  A well formed junction should have one incoming transition and two or more outgoing. ArgoUML does not enforce this, but an ArgoUML critic will complain about any junction that does not follow this rule.

• **Fork.** Add a fork pseudostate to the diagram.

  **Caution**

  A well formed fork should have one incoming transition and two or more outgoing. ArgoUML does not enforce this, but an ArgoUML critic will complain about any fork that does not follow this rule.

• **Join.** Add a join pseudostate to the diagram.

  **Caution**

  A well formed join should have one outgoing transition and two or more incoming. ArgoUML does not enforce this, but an ArgoUML critic will complain about any join that does not follow this rule.

• **CallState.** Add a callstate to the diagram. A call state is an action state that calls a single operation. Hence, the name of the operation being called is put in the symbol, along with the name of the classifier that hosts the operation in parentheses under it.

• **ObjectFlowState.** Add an objectflowstate to the diagram. An objectflowstate is an object that is input to or output from an action.

### 12.3.10. Deployment Diagram Specific Tools

Ten tools are provided specific to UML artifacts on deployment diagrams. The detailed properties of these artifacts are described in the section on deployment diagram artifacts (see Chapter 23, *Deployment Diagram Artifact Reference*).

**Note**

Remember that ArgoUML’s deployment diagrams are also used for component diagrams.

• **Node.** Add a node to the diagram. For convenience, when the mouse is over a selected node it displays four handles to left, right, top and bottom which may be dragged to form association relationships.

• **Node Instance.** Add a node instance to the diagram. For convenience, when the mouse is over a selected node instance it displays four handles to left, right, top and bottom which may be dragged to form link relationships.
• **Component.** Add a component to the diagram. For convenience, when the mouse is over a selected component it displays four handles to left, right, top and bottom which may be dragged to form dependency relationships.

• **Component Instance.** Add a component instance to the diagram. For convenience, when the mouse is over a selected component instance it displays four handles to left, right, top and bottom which may be dragged to form dependency relationships.

• **Generalization.** Add a generalization between two artifacts selected using button 1 (from the child to the parent).

• **Realization.** Add a realization between a class and an interface selected using button 1 motion (from the realizing class to the realized interface).

• **Dependency.** Add a dependency between two artifacts selected using button 1 motion (from the dependent artifact).

• **Association.** Add an association between two artifacts (node, component, class or interface) selected using button 1 motion (from the first artifact to the second artifact). There are 6 types of association offered here, see Figure 12.4, “The association tool selector”: association, aggregation and composition, and all these three can be bidirectional or unidirectional.

**Caution**

The constraint that associations between classes and interfaces must not be navigable from the interface still applies on deployment diagrams.

• **Object.** Add an object to the diagram. For convenience, when the mouse is over a selected object it displays four handles to left, right, top and bottom, which may be dragged to form link relationships.

• **Link.** Add a link between two artifacts (node instance, component instance or object) selected using button 1 motion.

### 12.4. The Broom

ArgoUML’s broom alignment tool is specialized to support the needs of designers in achieving the kind of alignment used in UML diagrams. It is common for designers to roughly align objects as they are created or by using simple movement commands. The broom is an easy way to precisely align objects that are already roughly aligned. Furthermore, the broom’s distribution options are suited to the needs of UML designers: making related objects appear evenly spaced, packing objects to save diagram space, and spreading objects out to make room for new objects. The broom also makes it easy to change from horizontal to vertical alignment or from left-alignment to right-alignment.

The T-shaped icon in ArgoUML’s diagram toolbar invokes the broom alignment tool. When the mouse button 1 is pressed while in broom-mode, the designer’s initial mouse movement orients the broom to face in one of four directions: north, south, east, or west. After that, mouse drag events cause the broom to advance in the chosen direction, withdraw, or grow in a lateral direction. Like a real-world push broom, the broom tool pushes diagram elements that come in contact with it. This has the effect of aligning objects along the face of the broom and provides immediate visual feedback (see the figure below). Unlike a real-world broom, moving backwards allows diagram elements to return to their original position. Growing the broom makes it possible to align objects that are not near each other. When the mouse button is released, the broom disappears and the moved objects are selected to make it easy to manipulate them further.
If the designer presses the space bar while using the broom, objects on the face of the broom are distributed (i.e., spaced evenly). ArgoUML’s broom supports three distribution modes: objects can be spaced evenly across the space that they use, objects can be packed together with only a small gap between them, or objects can be distributed evenly over the entire length of the broom’s face. Repeatedly pressing the space bar cycles among these three distribution modes and displays a brief message indicating the operation just performed: Space evenly, Pack tightly, Spread out and Original.

12.5. Selection Action Buttons

When the user selects an artifact in a UML diagram, several handles are drawn on it to indicate that it is selected and to provide user interface affordances to resize the node. ArgoUML also displays some “selection-action buttons” around the selected artifact. See the figure below for some examples of the handles and “selection-action buttons”. The two figures for a class differ because for creating the second one, the shift key has been depressed.

Selection-action buttons offer common operations on the selected object. For example, a class node has a button at 12-o’clock for adding a superclass, one at 6-o’clock for adding a subclass, and buttons at 3-o’clock and 9-o’clock for adding associations. These buttons support a “click or drag” interaction: a single click creates a new related class at a default position relative to the original class and creates a generalization or association; a drag from the button to an existing class creates only the generalization or association; and, a drag to an empty space in the diagram creates a new class at the mouse position and the generalization or association. ArgoUML provides some automated layout support so that clicking the subclass button will position the new classes so that they do not overlap.

Selection-action buttons are transparent. They have a visibly recognizable rectangular shape and size and they contain an icon that is the same as the icon used for the corresponding type of design element on the standard toolbar. However, these icons are unfilled line drawings with many transparent pixels. This allows selection-action buttons to be overlaid onto the drawing area without overly obscuring the diagram itself. Also, the buttons are only drawn when the mouse is over the selected artifact; if any part of the diagram is obscured, the mouse can simply be moved away to get a clearer view of the diagram.

12.6. Clarifiers

A key feature of ArgoUML are the critics, which run in parallel with the main ArgoUML tool. When they find a problem, they typically raise a to-do item, and also highlight the problem on the editing pane. The graphical techniques used for highlighting are called Clarifiers

- Note icon ( ). Displayed at the top left of an artifact indicates a critic of that artifact. Moving the mouse over the icon will pop up the critic headline.
• Colored wavy line ( ). Used for critics specific to sub-components of graphical artifacts. For example to underline attributes with a problem within a class.

• Solid colored line ( ). Not seen in ordinary editing, but used when a to-do item is highlighted from the to-do pane (see Chapter 14, The To-Do Pane) by button 1 double click. The solid line is used to show all the artifacts affected by the critic, for example all stimuli that are out of order.

12.7. The Drawing Grid

The editing pane is provided with a background grid which can be set in various styles or turned off altogether through the menu (see Section 10.5.4, “Adjust Grid”).

Whatever grid is actually displayed, placement of items on the diagram is always controlled by the setting for grid snap, which ranges from 4 to 32 pixels (see Section 10.5.5, “Adjust Grid Snap”).

12.8. The Diagram Tab

At the bottom of the editing pane is a small tab labeled as As Diagram. The concept is that a UML diagram can be displayed in a number of ways, for example as a graphical diagram or as a table. Each representation would have its own tab and be selected by button 1 click on the tab.

Earlier versions of ArgoUML did implement a tabular representation, but the current release only supports a diagram representation, so this tab does not have any function.

12.9. Pop-Up Menus

Within the editing pane, button 2 click over an artifact will bring up a pop-up menu with a variable number of main entries, many with a sub-menu.

12.9.1. Critiques

This sub-menu gives list of all the critics that have triggered for this artifact. Selection of a menu entry causes that entry to be highlighted in the to-do pane and its detailed explanation to be placed in the To-DoItem tab of the details pane. A solid colored line indicates the offending element.

12.9.2. Ordering

This menu controls the ordering of overlapping artifacts on the diagram. It is equivalent to the Re-order sub-menu of the Arrange menu (see Section 10.7.3, “Reorder”). There are four entries.

• Forward. The selected artifacts are moved one step forward in the ordering hierarchy with respect to other artifacts they overlap.

• Backward. The selected artifacts are moved one step back in the ordering hierarchy with respect to other artifacts they overlap.

• To Front. The selected artifacts are moved to the front of any other artifacts they overlap.

• To Back. The selected artifacts are moved to the back of any other artifacts they overlap.

12.9.3. Add
This sub-menu only appears for artifacts that can have notes attached (class, interface, object, state, pseudostate) or have operations or attributes added (class, interface). There are at most three entries.

- **New Attribute.** Only appears where the selected artifact is a class. Creates a new attribute on the artifact.

- **New Operation.** Only appears where the selected artifact is a class or interface. Creates a new operation on the artifact.

- **New Comment.** Attaches a new comment to the selected artifact.

- **Add All Relations.** Only appears where the selected artifact is a class or interface. Makes all relations visible that exist in the model and that are connected to the selected artifact.

- **Remove all Relations.** Only appears where the selected artifact is a class or interface. Removes all connected relations from the diagram (without removing them from the model).

### 12.9.4. Show

This sub-menu only appears with certain artifacts. It is completely context dependent. There are many possible entries, depending on the selected artifact and its state.

- **Hide Extension Point Compartment.** Only appears when the extension point compartment of a use case is displayed. Hides the compartment.

- **Show Extension Point Compartment.** Only appears when the extension point compartment of a use case is hidden. Displays the compartment.

- **Hide All Compartments.** Only appears when both attribute and operation compartments are displayed on a class or object. Hides both compartments.

- **Show All Compartments.** Only appears when both attribute and operation compartments are hidden on a class or object. Displays both compartments.

- **Hide Attribute Compartment.** Only appears when the attribute compartment of a class or object is displayed. Hides the compartment.

- **Show Attribute Compartment.** Only appears when the attribute compartment of a class or object is hidden. Displays the compartment.

- **Hide Operation Compartment.** Only appears when the operation compartment of a class or object is displayed. Hides the compartment.

- **Show Operation Compartment.** Only appears when the operation compartment of a class or object is hidden. Displays the compartment.

- **Hide Enumeration Literal Compartment.** Only appears when the enumeration literal compartment of an enumeration is displayed. Hides the compartment.

- **Show Enumeration Literal Compartment.** Only appears when the enumeration literal compartment of an enumeration is hidden. Displays the compartment.

- **Show All Edges.** Only appears on a class. Displays all associations (to shown artifacts) that are not shown yet. This is the same function as the "add to Diagram" on the association in the explorer context menu. Currently.
• **Hide All Edges.** Only appears on a class. Hides all associations. This is the same function as “Remove from Diagram” on all the associations of this class.

• **Hide Stereotype.** Only appears when the Stereotype of a package is displayed. Hides the stereotype.

• **Show Stereotype.** Only appears when the Stereotype of a package is hidden. Displays the stereotype.

• **Hide Visibility.** Only appears when the visibility of a package is displayed. Hides the visibility.

• **Show Visibility.** Only appears when the visibility of a package is hidden. Displays the visibility.

### 12.9.5. Modifiers

This sub-menu only appears with class, interface, package and use case artifacts. It is used to set or clear the values of the various modifiers available.

• **Abstract.** Set for an abstract artifact.

• **Leaf.** Set for a final artifact, i.e. one with no subartifacts.

• **Root.** Set for a root artifact, i.e. one with no superartifacts.

• **Active.** Set for a artifact with dynamic behavior.

**Note**

This really ought to be set automatically for artifacts with state machines or activity diagrams.

### 12.9.6. Multiplicity

This sub-menu only appears with association artifacts, when clicking at one end of the association. It is used to control the multiplicity at the end of the association nearest the mouse click point. There are only four entries, a sub-set of the range of multiplicities that are available through the property sheet of a association end (see Section 17.6, “Association End”).

- 1
- 0..1
- 1..*
- 0..*

### 12.9.7. Aggregation

This sub-menu only appears with association artifacts, when clicking at one end of the association. It is
used to control the aggregation at the end of the association nearest the mouse click point. There are three entries.

- **none.** Remove any aggregation.
- **aggregate.** Make this end a shared aggregation (loosely known as an “aggregation”).
- **composite.** Make this end a composite aggregation (loosely known as a “composition”).

**Caution**

UML requires that an end with a composition relationship must have a multiplicity of 1 (the default).

### 12.9.8. Navigability

This sub-menu only appears with association artifacts, when clicking at one end of the association. It is used to control the navigability of the association. There are three entries.

- **bidirectional.** Make the association navigable in both directions.
- **<class1> to <class2>.** Make the association navigable only from <class1> to <class2>. In other words <class1> can reference <class2> but not the other way round.
- **<class2> to <class1>.** Make the association navigable only from <class2> to <class1>. In other words <class2> can reference <class1> but not the other way round.

**Note**

UML does permit an association to be non-navigable in both directions. ArgoUML will allow this, but you will have to set each of the association ends navigation property, reached from the property tab of the association - and the diagram does not show any arrows in this case.

This is considered bad design practice (it will trigger a critic in ArgoUML), so is only of theoretical interest.

**Note**

UML does not permit navigability from an interface to a class. ArgoUML does not prevent this.

### 12.10. Notation

Notation is the textual representation on the diagram of a modelelement or its properties.

#### 12.10.1. Notation Languages

ArgoUML supports showing notation in different languages. By default, all text is shown in UML nota-
...ination, but the menus contain an item to select between Java and UML. With plugin modules, it is even possible to select other languages, such as C++ and PHP, but the current (0.22) version of ArgoUML does not show any difference.

Figure 12.7, “A class in UML notation” shows a class in UML notation, while Figure 12.8, “A class in Java notation” shows the same class in Java notation.

Figure 12.7. A class in UML notation

Figure 12.8. A class in Java notation

12.10.2. Notation Editing on the diagram

Most text shown on a diagram may be edited by double-clicking button 1 on the text. This causes a edit box to be shown, with the previous text selected, ready for amending.

Also, the status bar of ArgoUML (i.e. the small area at the bottom of the ArgoUML window), shows an help text that indicates the syntax of the text to be entered. Text entry can be concluded by pressing F2, or for single-line fields, by pressing the enter key. Additionally, editing can be concluded by clicking somewhere in the diagram outside the edit area.

Editing notation on the diagram is a very powerful way to enter a lot of model-information in a very compact way. It is e.g. possible to create an operation, its stereotype, all parameters and their types, and operation properties (visibility, concurrency), all at once by typing:

+Order(customerID : int,items : List) : void (sequential)

An association (e.g. between two classes) is showing many texts close to its middle and ends, so its deserves some extra explanation. Figure 12.9, “A couple of associations with adornments” shows two associations to clarify the following:

Figure 12.9. A couple of associations with adornments

The association on the right shows that invisible fields where text can be entered become visible once the modelement is selected. The fields are indicated by blue rectangles - double-click on them with mouse button 1 to start editing.

The visibility (the +, -, # or ~) is shown together with the association-end name, but it is not shown for an unnamed association end.

Likewise, the multiplicity is not shown if it is 1.

The example figure does not demonstrate this, but stereotypes of an association are shown on the diagram, but are not editable. And stereotypes of association-ends are shown together with the association-end name.

12.10.3. Notation Parsing
(to be written)
Chapter 13. The Details Pane

13.1. Introduction

Figure 13.1, “Overview of the details pane” shows the ArgoUML window, with the details pane highlighted.

Figure 13.1. Overview of the details pane

For any artifact within the system, this pane is where all its associated data is viewed and entered.

The Pane has a series of tabs at the top, which are selected by button 1 click. The body of a tab is a menu of items to be checked, selected or entered specific to the particular tab selected.

Of these, the Properties Tab is by far the most complex, with a different presentation for each artifact within the system. The detailed descriptions of the properties tab for each artifact are the subject of separate chapters covering the artifacts that may appear on the various diagrams (see Chapter 16, Top Level Artifact Reference through Chapter 23, Deployment Diagram Artifact Reference).

13.2. To Do Item Tab

This tab provides control over the various to-do items created by the user, or raised automatically by the ArgoUML critics (discussed in more detail in the section on the Critique menu? see Section 10.9, “The Critique Menu”). Figure 13.2, “Example of the To Do Item tab on the properties pane” shows a typical pane. The to-do item is selected with button 1 in the to-do pane (see Chapter 14, The To-Do Pane) or by using the Critiques context sensitive pop-up menu on the editing pane.

Figure 13.2. Example of the To Do Item tab on the properties pane

Customization of the critics behaviour is possible through the Browse critics... menu (see Section 10.9.4, “Browse Critics...”).

The body of the tab describes the problem found by the critic and outlines how it can be fixed. To the left are four buttons.

- New To Do Item... This launches a dialog box (see Figure 13.3, “Dialog box for New To Do Item”), which allows you to create your own to-do item, with its own headline (which appears in the to-do pane), priority for the to-do pane, reference URL and detailed description for further information.

Figure 13.3. Dialog box for New To Do Item

- Resolve Item... This pops up a dialog allowing the user to resolve the selected to-do item (see Figure 13.4, “Dialog box for Resolve Item ”). This is an important dialog, because it allows you to deal with to-do items in ways other than the recommendation of the to-do item (which is the whole
point of their being advisory).

This dialog box is intended to be used for the following reasons: deleting todo items that were manually created, preventing a single critic to trigger on a single object, and dismissing categories of todo items by lowering design concerns or design goals.

**Figure 13.4. Dialog box for Resolve Item**

At the top are three radio-buttons, of which by default the last is selected, labeled 1) *It is not relevant to my goals*, 2) *It is not of concern at the moment*, and 3) *Reason given below*. If you choose the third of these you should enter a reason in the main text box.

**Tip**

If you wish to resolve a to-do item (that is generated by a critic) by following its recommendations, just make the recommended changes and the to-do item will disappear of its own accord. There is no need to use this dialog.

**Warning**

The V0.20 version of ArgoUML implementation is incomplete: The reason given is not stored when the project is saved. And there is no way to retrieve todo items that were resolved. So, it is not usefull to give a reason at all.

When a todo item generated by a critic is resolved, then there is no way to undo this (unless by re-creating the object that triggered the critic).

- **Send Email To Expert...** Activating this tool allows the user to send an Email to an expert asking for advice. This works like clicking a "mailto:users@argouml.tigris.org?subject=[critic header]" link in your webbrowser.

- **Snooze Critic** This suspends the activity of the critic that generated the current to-do item. The to-do item (and all others generated by the critic) will disappear from the to-do pane.

The critic will wake up after a period of time. Initially this period is 10 minutes, but it doubles on each successive application of the Snooze button. The critic can be awakened explicitly through the Critique > Browse Critics... menu (see Section 10.9.4, “Browse Critics…”).

**Tip**

Some common critics can fire the whole time as you build a big diagram. Some users find it useful to snooze these critics until the diagram has been completed.

**13.2.1. Wizards**

Some of the more common critics have a “wizard” available to help in fixing the problem. The wizard comprises a series of pages (one or more) in the ToDo Item tab that step you through the changes. Start the wizard by clicking the Next> button.
The wizard is driven through the first three buttons at the bottom of the **ToDo Item** tab.

- **<Back**. This will take you back to the previous step in the wizard. Grayed out if this is the first step.
- **Next>**. This will take you back to the next step in the wizard. Grayed out if this is the last step.
- **Finish**. This will commit the changes you have made through the wizard in previous steps, and/or use the defaults for all next steps.

**Note**
Not all to-do items have wizards. If there is no wizard all three buttons will remain grayed out.

The ArgoUML wizards are *non-modal*, i.e. once started, you may select other todo items, or do some other actions, and all the while the wizard will remember where it was, so if you return to the todo item, the wizard will indicate the same step it was on when you left it.

### 13.2.2. The Help Button

There is one remaining button at the bottom of the **ToDo Item** tab, labeled **Help**. This will fire up a browser to a URL with further help.

**Warning**
In the V0.20 release of ArgoUML the URLs are generally invalid. The few that are valid have no information.

### 13.3. Properties Tab

Through this tab, the properties of artifacts selected in the explorer or editing pane may be set. The properties of an artifact may be displayed in one of the following ways:

1. Selection of the artifact in the explorer or editing panes, followed by selection of the properties tab in the details pane; or

2. Navigation buttons cause different artifacts to be selected. I.e. the **Go Up** button on the properties tab, the **Navigate Back** and **Navigate Forward** buttons in the main toolbar, and the various menu-items under **Edit - Select**.

Figure 13.6. “A typical Properties tab on the details pane” shows a typical properties tab for an artifact in ArgoUML (in this case a class).
At the top left is the icon and name of the type of artifact (i.e. the UML metaclass, not the actual name of this particular artifact). In this example the property tab is for a class.

To the right of this is a toolbar of icons relevant to this property tab. The first one is always navigation `Go up`. The last is always `Delete` to delete the selected artifact from the model. The ones in between depend on the artifact.

The remainder of the tab comprises fields, laid out in two or three columns. Each field has a label to its left. The fields may be text boxes, text areas, drop down selectors, radio boxes and check boxes. In most (but not all cases) the values can be changed. In the case of text boxes this is sometimes by just typing the required value.

However for many text boxes and text areas, data entry is via a context sensitive pop-up menu (using button 2 click), which offers options to add a new entry, delete an entry or move entries up and down (in text areas with multiple entries).

The first field is almost always a text field `Name`, where the name of the specific artifact can be entered. The remaining fields vary depending on the artifact selected.

The detailed property sheets for all ArgoUML artifacts are discussed in separate chapters for each of the diagram types (use case diagram (Chapter 17, Use Case Diagram Artifact Reference), class diagram (Chapter 18, Class Diagram Artifact Reference), sequence diagram (Chapter 19, Sequence Diagram Artifact Reference), statechart diagram (Chapter 20, Statechart Diagram Artifact Reference), collaboration diagram (Chapter 21, Collaboration Diagram Artifact Reference), activity diagram (Chapter 22, Activity Diagram Artifact Reference), deployment diagram (Chapter 23, Deployment Diagram Artifact Reference). Property sheets for artifacts that are common to all diagram types have their own chapter (Chapter 16, Top Level Artifact Reference).

**Caution**

ArgoUML will always try to squeeze all fields on to the property sheet. If the size of the property tab is too small, it may become unusable. The solution is to either enlarge the property tab by enlarging the main window, or by moving the dividers to left and top.

### 13.4. Documentation Tab

Within the UML 1.4 standard, all artifacts are children of the `Element` metaclass. The `Element` metaclass defines a tagged value `documentation` for comment, description or explanation of the element to which it is attached. Since this tagged value applies to every artifact, it is given its own tab in the details pane, rather than being part of the `Tagged Values` tab.

Figure 13.7, “A typical Documentation tab on the details pane” shows a typical documentation tab for an artifact in ArgoUML.

**Figure 13.7. A typical Documentation tab on the details pane**

As you can see, many more fields have been added to the Documentation field alone. The other fields similarly store their information under tagged values: `author`, `version`, `since`, `deprecated`, `see`.

The fields on this tab are the same for all artifacts.

Since UML comments are a kind of documentation, they are also shown on this tab, with name and
body.

- **Author**: A text box for the author of the documentation.
- **Version**: A text box for the version of the documentation.
- **Since**: A text box to show how long the documentation has been valid.
- **Deprecated**: A check box to indicate whether this artifact is deprecated (i.e. planned for removal in future versions of the design model).
- **See**: Pointers to documentation outside the system.
- **Documentation**: Literal text of any documentation.
- **Comment Name**: The names of all comments attached to the modelelement.
- **Body**: The bodies of all comments attached to this modelelement.

**Tip**

ArgoUML is not primarily a documentation system. For artifacts that require heavy documentation, notably use cases, the use of the **See** field to point to external documents is more practical.

### 13.5. Presentation Tab

This tab provides some limited control over the graphical representation of artifacts in the diagram in the editing pane.

Artifacts that do not have any specific direct graphical representation on the screen (beyond their textual description) do not have style tabs of their own. For example the style sheet of an operation on a class will be downlighted.

Style sheets vary a little from artifact to artifact, but Figure 13.8, “A typical Presentation tab on the details pane” shows a typical style tab for an artifact in ArgoUML (in this case a class).

**Figure 13.8. A typical Presentation tab on the details pane**

There may be further fields in some cases, e.g. for a package, but most fields are common to many artifacts.

- **Path** This checkbox allow to display or hide the path in front of the name of the modelelement. It is shown in UML notation with :: seperators. E.g. the ArgoUML Main class would be shown as: `org::argouml::application::Main`.
- **Attributes** This checkbox allows to hide or show the attributes compartment of a class.
- **Operation** This checkbox allows to hide or show the operations compartment of a class or interface.
• **Stereotype** This checkbox allows to reveal or hide the stereotypes of a package, shown above the name.

• **Visibility** This checkbox allows to hide the visibility of a package. The visibility is shown in UML notation as +, -, # or ~.

• **Extension Points** This checkbox allows to reveal or hide the extensions points compartment of a usecase.

• **Bounds:** This defines the corners of the bounding box for a 2D artifact. It comprises four numbers separated by commas. These four numbers are respectively: i) the X coordinate of the upper left corner of the box; ii) the Y coordinate of the upper left corner of the box; iii) the width of the box; and iv) the height of the box. All units are pixels on the editing pane.

  This field has no effect on 1D artifacts that link other artifacts (associations, generalizations etc), since their position is constrained by their connectedness. In this case the field is downlighted.

• **Fill:** This drop-down selector specifies the fill color for 2D artifacts. It is not present for line artifacts. Selecting No Fill makes the artifact transparent. Selecting Custom allows to create other colors then the ones listed. It causes the color selector dialog box to appear, see Figure 13.9, “The Custom Fill/Line Color dialog box”.

• **Line:** This drop-down selector specifies the line color for artifacts. Selecting No Fill makes the artifact transparent. Selecting Custom allows to create other colors then the ones listed. It causes the color selector dialog box to appear, see Figure 13.9, “The Custom Fill/Line Color dialog box”.

• **Shadow:** This drop-down selector specifies the width of the shadow (if any) for 2D artifacts. It is not present for line artifacts.

**Figure 13.9. The Custom Fill/Line Color dialog box**

**Figure 13.10. The Custom Fill/Line Color dialog box**

**Figure 13.11. The Custom Fill/Line Color dialog box**

### 13.6. Source Tab

This tab shows the source code that will be generated for this artifact, in the selected language. ArgoUML generates the code e.g. for classes and interfaces. The code shown here, may be saved in the indicated files with the aid of the functions in the Generation menu.

**Figure 13.12. The Source Tab of a class.**

Any code you add will be lost - that is not the intention of ArgoUML - use an IDE instead.
The dropdown at the right allows selection of the output file. This function is not very useful for languages that generate all code for a class within one file, but serves its purpose for e.g. C++, where a .h and .cpp file are generated. See the figure below.

Figure 13.13. A C++ example.

13.7. Constraints Tab

Constraints are one of the extension mechanisms provided for UML. ArgoUML is equipped with a powerful constraint editor based on the Object Constraint Language (OCL) defined in the UML 1.4 standard.

Caution

The OCL editor implementation for ArgoUML V0.20 doesn't support OCL constraints for elements other than Classes and Features.

This is something of a general restriction of OCL. Although the UML specification claims that there may be a constraint for every model element, the OCL specification only defines classes/interfaces and operations as allowable contexts.

It is not before OCL 2.0 that a more general definition of allowable contexts is introduced. The key issue is that for each context definition you need to define what is the contextual Classifier, i.e., the classifier that will be associated with the self keyword. The creators of the OCL specification claim that this is not an issue for the OCL specification, but rather for UML or some integration task force. Conversely, it seems that the UML specification people seem to expect this to be defined in the OCL specification (which is why we did a first step in that direction in OCL 2.0).

So, to cut a long story short, it appeared that the simplest solution for ArgoUML at the moment would be to enable the OCL property panel only for those model elements for which there actually exists a definition of the contextualClassifier in OCL 1.4. These are (s. above) Class/Interface and Feature.

The standard pre-defines a small number of constraints (for example the xor constraint over a set of associations indicating that only one may be manifest for any particular instance).

The standard also envisages a number of circumstances where general purpose constraints may be useful:

* To specify invariants on classes and types in the class model;
* To specify type invariants for stereotypes;
* To describe pre-conditions and post-conditions on operations and methods;
* To describe guards;
* As a navigation language; and
* To specify constraints on operations.
Figure 13.14, “A typical Constraints tab on the details pane” shows a typical constraint tab for an artifact in ArgoUML (in this case a class).

**Figure 13.14. A typical Constraints tab on the details pane**

Along the top of the tab are a series of icons.

- **New Constraint.** This creates a new constraint and launches the constraint editor in the Constraints tab for that new constraint (see Section 13.7.1, “The Constraint Editor”). The new constraint is created with a context declaration for the currently selected artifact.

  **Warning**

  It seems logical, that when a new constraint is created, it needs to be edited. But ArgoUML V0.20 fails to start the OCL editor upon creation; you have to do this by primo selecting the new constraint first, secundo rename it, and tertio press the **Edit Constraint** button. It is essential for successfully creating a constraint to follow these 4 steps accurately: create, select, rename, edit. The step to rename is necessary, because the validity check will refuse the constraint if its name differs from the name mentioned in the constraint text. For the same reason, renaming a constraint afterwards is impossible.

- **Delete Constraint.** The constraint currently selected in the Constraint Name box (see below) is deleted.

  **Caution**

  In V0.20 of ArgoUML this button is not downlighted when it is not functional, i.e. when no constraint is selected.

- **Edit Constraint.** This launches the constraint editor in the Constraints tab (see Section 13.7.1, “The Constraint Editor”). The editor is invoked on the constraint currently selected in the Constraint Name box.

  **Caution**

  In V0.18 of ArgoUML this button is not downlighted when it is not functional, i.e. when no constraint is selected.

- **Configure Constraint Editor.** This a dialog to configure options in the constraint editor (see Figure 13.15, “Dialog box for configuring constraints”).

**Figure 13.15. Dialog box for configuring constraints**

The dialog box has a check box for the following option.

- **Check type conformance of OCL constraints.** OCL is strictly typed. At the early stages of design it may be helpful to disable type checking, rather than follow through all the de-
tailed specification needed to get type consistency.

At the bottom are two buttons, labeled OK (to accept the option changes) and Cancel (to discard the changes).

The main body of the constraints tab comprises two boxes, a smaller to the left and a larger one to the right. The two are separated by two small arrow buttons which control the size of the boxes.

- **Shrink Left.** Button 1 click on this icon shrinks the box on the left. Its effect may be reversed by use of the **Shrink Right** button (see below).

- **Shrink Right.** Button 1 click on this icon shrinks the box on the right. Its effect may be reversed by use of the **Shrink Left** button (see above).

Finer control can be achieved by using button 1 motion to drag the dividing bar to left and right.

The box on the left is titled **Constraint Name** and lists all the constraints (if any) so far defined for the selected artifact. A constraint may be selected by button 1 click.

The box on the right is labeled **Preview** and contains the text of the constraint. This box only shows some contents if a constraint is selected. Where a constraint is too large for the box, a scroll bar is provided to the right.

### 13.7.1. The Constraint Editor

This is invoked through the use of the **Edit Constraint** button on the main **Constraints** tab. The constraint editor takes up the whole tab (see Figure 13.16, “Dialog box for configuring constraints”).

**Figure 13.16. Dialog box for configuring constraints**

Along the top of the tab are a series of icons.

- **Cancel Edit Constraint.** This exits the constraint editor without saving any changes and returns to the main Constraints tab.

- **Check OCL Syntax.** This button invokes a full syntax check of the OCL written in the editor. If the syntax is valid, the constraint is saved, and control returns to the main Constraints tab. If the syntax is not valid, a dialog box explains the problem.

  **Warning**

  Whether type checking is included should be configurable with the **Configure Constraint Editor** button (see below). But ArgoUML V0.20 does always check, and refuses to accept any constraint with the slightest error.

- **Configure Constraint Editor.** This a dialog to configure options in the constraint editor. It is also available in the main Constraints tab and is discussed in detail there (see Section 13.7, “Constraints Tab”).

---

130
To the right of the toolbar is a check box labeled Syntax Assistant (unchecked by default), which will enable the syntax assistant in the constraint editor.

If the syntax assistant is enabled, six drop down menus are provided in a row immediately below the toolbar. These provide standard templates for OCL that, when selected, will be inserted into the constraint being edited.

The syntax assistant can be made floating in a separate window by button 1 motion on the small divider area to the left of the row of drop-down menus.

- **General.** General OCL constructors. Entries: inv (inserts an invariant); pre (inserts a precondition); post (inserts a post-condition); self (inserts a self-reference); @pre (inserts a reference to a value at the start of an operation); and result (inserts a reference to a previous result).

- **Basic Operators.** Relational operators and parentheses. Entries: =; <=; <; >=; and ()

- **Numbers.** Arithmetic operators and functions. Entries: +; -; *; /; mod; div; abs; max; min; round; and floor.

- **Strings.** String functions. Entries: concat; size; toLower; toUpper; and substring.

- **Booleans.** Logical functions. Entries: or; and; xor; not; implies; and if then else.

- **Collections.** Operators and functions on collections (bags, sets and sequences). The large number of functions are organized into sub-groups.

  - **General.** Functions that apply to all types of collection. Entries: Collection {} (insert a new collection); Set {} (insert a new set); Bag {} (insert a new bag); Sequence {} (insert a new sequence); size; count; isEmpty; notEmpty; includes; includesAll; iterate; exists; forAll; collect; select; reject; union; intersection; including; excluding; and sum.

  - **Sets.** Operators and functions that apply only to sets. Entries: – (set difference); and symmetricDifference.

  - **Sequences.** Functions that apply to sequences. Entries: first; last; at; append; prepend; and subSequence.

The remainder of the tab comprises a writable text area containing the text to be edited. The mouse buttons have their standard behavior within an editable text area (see Section 8.2, “General Mouse Behavior in ArgoUML”).

In addition, cut, copy and paste operations may be invoked through the keyboard shortcuts Ctrl-X, Ctrl-C and Ctrl-V respectively.

### 13.8. Stereotype Tab

This tab shows the available and applied stereotypes for the currently selected modeled element. It consists of 2 panels and 2 buttons. The buttons allow to move the stereotypes from one list to the other.

**Figure 13.17. An example of a stereotype tab for a class.**

In the lists, between [] the baseclass of the stereotypes is shown. E.g. in the figure above, the thread
13.9. Tagged Values Tab

Tagged values are another extension mechanism provided by UML. The user can define name-value pairs to be associated with artifacts which define properties of that artifact. The names are known as *tags*. UML pre-defines a number of tags that are useful for many of its artifacts.

**Note**

The tag documentation is defined for the top UML metaclass, *Element* and is so available to all artifacts. In ArgoUML documentation values are provided through the *Documentation* tab, rather than by using the *Tagged Values* tab.

The *Tagged Values* tab in ArgoUML comprises a two column table, with a combo-box on the left to select the tag definition and an editable box on the right for the associated value. There is always at least one empty row available for any new tag.

The button at the top of this tab allows creation of a new tag definition. After clicking this button, go to the properties tab first to set the name of the new tag definition.

The mouse buttons have their standard behavior within the editable value area (see Section 8.2, “General Mouse Behavior in ArgoUML”). In addition, when in the value field, cut, copy and paste operations may be invoked through the keyboard shortcuts Ctrl-X, Ctrl-C and Ctrl-V respectively.

13.10. Checklist Tab

Conducting design reviews and inspections is one of the most effective ways of detecting errors during software development. A design review typically consists of a small number of designers, implementers, or other project stakeholders holding a meeting to review a software development artifact. Many development organizations have developed checklists of common design problems for use in design review meetings. Recent research indicated that reviewers inspecting code without meeting, making use of these checklists, are just as effective as design review meetings.

Hence, a checklist feature has been added to ArgoUML, that is much in the spirit of design review checklists. However, ArgoUML's checklists are integrated into the design tool user interface and the design task.

A software designer using ArgoUML can see a review checklist for any design element. The “Checklist” tab presents a list of check-off items that is appropriate to the currently selected design element. For example, when a class is selected in a design diagram, the checklist tab shows items that prompt critical thinking about classes. See the figure below. Designers may check off items as they consider them. Checked items are kept in the list to show what has already been considered, while unchecked items prompt the designer to consider new design issues. ArgoUML supplies many different checklists with many possible items.

**Figure 13.18. An example of a checklist for a class.**

**Caution**

In the V0.20 release of ArgoUML, this tab is not completely implemented. E.g. the checks are not saved.
Chapter 14. The To-Do Pane

14.1. Introduction

Figure 14.1, “Overview of the to-do pane” shows the ArgoUML window with the to-do pane highlighted.

Figure 14.1. Overview of the to-do pane

This pane provides access to the advice that comes from the critics processes running within ArgoUML. A selector box at the top allows a choice of how the data is presented, a button allows the display of the hierarchy to be changed, and there is an indicator of the number of to-do items identified.

More information on critics can be found in the discussion of the Critique menu (see Section 10.9, “The Critique Menu”).

14.2. Mouse Behavior in the To-Do Pane

Behavior of the mouse in general, and the naming of the buttons is covered in the chapter on the overall user interface (see Chapter 8, Introduction).

14.2.1. Button 1 Click

This action is generally used to select an item for subsequent operations.

Within the hierarchical display, elements which have sub-hierarchies may be indicated by when the hierarchy is hidden and when the hierarchy is open.

When these icons are displayed, the display of the hierarchy is toggled by button 1 click on these icons.

Button 1 click over the headline of any to-do item will cause its details to be shown in the To Do Item tab of the details pane. That tab is automatically selected if it is not currently visible.

14.2.2. Button 1 Double Click

When applied to the folder icon alongside a hierarchy category, this will cause the display of that hierarchy to be toggled.

When applied to a headline, button 1 double click will show the diagram for the artifact to which the to-do item applies in the editing pane and select the artifact on the diagram using an appropriate clarifier (the artifact may be highlighted, underlined with a wavy line or surrounded by a colored box as appropriate).

14.2.3. Button 2 Actions

There are no button 2 functions in the to-do pane.

14.2.4. Button 2 Double Click
There are no button 2 functions in the to-do pane.

### 14.3. Presentation Selection

At the top of the pane is a drop-down selector controlling how the to-do items are presented. The to-do items may be presented in six different ways. This setting is not stored persistently, i.e. it is on its default value when ArgoUML is started.

- **By Priority.** This is the default setting. The to-do items are organized into three hierarchies by priority: High, Medium and Low. The priority associated with the to-do items generated by a particular critic may be altered through the Critique > Browse Critics... menu (see Section 10.9.4, “Browse Critics...”).

- **By Decision.** The to-do items are organized into 17 hierarchies by design issue: Uncategorized, Class Selection, Behavior, Naming, Storage, Inheritance, Containment, Planned Extensions, State Machines, Design Patterns, Relationships, Instantiation, Modularity, Expected Usage, Methods, Code Generation and Stereotypes. The details of the critics in each category are discussed in Section 10.9.2, “Design Issues...”.

- **By Goal.** ArgoUML has a concept that critics may be grouped according to the user goals they affect. This presentation groups the to-do items into hierarchies by goal.

  **Caution**

  In the current release of ArgoUML there is only one goal, Unspecified and all to-do items will appear under this heading.

- **By Offender.** The to-do items are organized into a hierarchy according to the artifact that caused the problem. Todo items that were manually created with the "New ToDo item" button (i.e. not by a critic), are not listed here.

- **By Poster.** The to-do items are organized into a hierarchy according to which critic generated the to-do item. The class name of the critic is listed instead of just its headline name since the former is guaranteed to be a unique name.

- **By Knowledge Type.** ArgoUML has the concept that a critic reflects a deficiency in a category of knowledge. This presentation option groups the critics according to their knowledge category: Designer's, Correctness, Completeness, Consistency, Syntax, Semantics, Optimization, Presentational, Organizational, Experiencial and Tool. The former category (Designer's) contains the manually entered todo items.

### 14.4. Item Count

To the right of the flat/hierarchical button is a count of the number of to-do items currently found. It will be highlighted in yellow when the number of to-do items grows above 50 todo items, and red when above 100.
Chapter 15. The Critics

15.1. Introduction

The key feature that distinguishes ArgoUML from other UML CASE tools is its use of concepts from cognitive psychology. The theory behind this is well described in Jason Robbins' PhD dissertation [http://argouml.tigris.org/docs/robbins_dissertation/].

Critics are one of the main ways in which these ideas are implemented. Running in the background they offer advice to the designer which may be accepted or ignored. A key point is that they do not impose a decision on the designer.

Note

The critics are asynchronous processes that run in parallel with the main ArgoUML tool. Changes typically take a second or two to propagate as the critics wake up.

15.1.1. Terminology

The critics are background processes, which evaluate the current model according to various “good” design criteria. There is one critic for every design criterion.

The output of a critic is a critique—a statement about some aspect of the model that does not appear to follow good design practice.

Finally a critique will generally suggest how the bad design issue it has identified can be rectified, by raising a to-do item.

15.1.2. Design Issues

ArgoUML categorizes critics according the the design issue they address (some critics may be in more than one category). At present there are 16 such categories.

Within this manual the descriptions of critics are grouped in sections by design issue.

15.2. Uncategorized

These are critics that do not fit into any other category.

ArgoUML has no critics in this category. Maybe some will be added in later versions.

15.3. Class Selection

These are critics concerning how classes are chosen and used.

ArgoUML has the following critics in this category.

15.3.1. Wrap DataType

DataTypes are not full classes within UML 1.4. They can only have enumeration literals as values, and only support query operations (that is operations that do not change the DataType's state).
DataTypes cannot be associated with classes, unless the DataType is part of a composite (black diamond) aggregation. Such an association reflects the tight binding of a collection of DataType instances to a class instance. In effect such a DataType is an attribute of the class with multiplicity.

Good OOA&D depends on careful choices about which entities to represent as full objects and which to represent as attributes of objects.

There are two options to fix this problem.

- Replace the DataType with a full class.
- or change the association aggregation to composite relationship at the DataType end.

### 15.3.2. Reduce Classes in diagram <diagram>

Suggestion to improve readability by having fewer classes on a diagram. If one class diagram has too many classes it may become very difficult for humans to understand. Defining an understandable set of class diagrams is an important part of your design.

The Wizard of this critic allows setting of the threshold, i.e. the maximum number of classes allowed before this critic fires.

**Caution**

This number is not stored persistently, and there is no way to reduce it after it has been set higher, except by creating more classes until the critic fires again. Restarting ArgoUML resets this number to its default: 20.

### 15.3.3. Clean Up Diagram

Suggestion that the diagram could be improved by moving artifacts that are overlapping.

### 15.4. Naming

These are critics concerning the naming of artifacts. The current version of ArgoUML has 18 critics in this category.

#### 15.4.1. Resolve Association Name Conflict

Suggestion that two association names in the same namespace have the same name. This is not permitted in UML.

#### 15.4.2. Revise Attribute Names to Avoid Conflict

Suggestion that two attribute names of a class have the same name. This is not permitted in UML.

**Note**

The problem may be caused by inheritance of an attribute through a generalization relationship.
15.4.3. Change Names or Signatures in an Artifact

Two operations in <artifact> have the same signature. This means their name is the same, and the list of parameters has the same type.

Where there are conflicting signatures, correct code cannot be generated for mainstream OO languages. It also leads to very unclear semantics of the design.

In comparing signatures, this critic considers:

1. the name;
2. the list of in, out and in-out parameter types in order; and

Only if these all match in both type and order, will the signatures be considered as the same.

This follows the line of Java/C++ in ignoring the return parameters for the signature. This may be unsatisfactory for some functional OO languages.

Note

Some purists would argue that the comparison should really differentiate between in, out and in-out parameters. However no practical programming language can do this when resolving an overloaded method invocation, so this critics lumps them all together.

15.4.4. Duplicate End (Role) Names for an Association

The specified association has two (or more) ends (roles) with the same name. One of the well-formedness rules in UML 1.4 for associations, is that all end (role) names must be unique.

This ensures that there can be unambiguous reference to the ends of the association.

To fix this, manually select the association and change the names of one or more of the offending ends (roles) using the button 2 pop-up menu or the property sheet.

15.4.5. Role name conflicts with member

A suggestions that good design avoids role names for associations that clash with attributes or operations of the source class. Roles may be realized in the code as attributes or operations, causing code generation problems.

15.4.6. Choose a Name (Classes and Interfaces)

The class or interface concerned has been given no name (it will appear in the model as anon). Suggestion that good design requires that all interfaces and classes are named.

15.4.7. Choose a Unique Name for an Artifact (Classes and Interfaces)

Suggestion that the class or interface specified has the same name as another (in the namespace), which is bad design and will prevent valid code generation.
15.4.8. Choose a Name (Attributes)

The attribute concerned has been given no name (it will appear in the model as (anon Attribute)). Suggestion that good design requires that all attributes are named.

15.4.9. Choose a Name (Operations)

The operation concerned has been given no name (it will appear in the model as (anon Operation)). Suggestion that good design requires that all operations are named.

15.4.10. Choose a Name (States)

The state concerned has been given no name (it will appear in the model as (anon State)). Suggestion that good design requires that all states are named.

15.4.11. Choose a Unique Name for a (State related) Artifact

Suggestion that the state specified has the same name as another (in the current statechart diagram), which is bad design and will prevent valid code generation.

15.4.12. Revise Name to Avoid Confusion

Two names in the same namespace have very similar names (differing only by one character). Suggestion this could potentially lead to confusion.

Caution

This critic can be particularly annoying, since at times it is useful and good design to have a series of artifacts var1, var2 etc.

It is important to remember that critics offer guidance, and are not always correct. ArgoUML lets you dismiss the resulting to-do items through the to-do pane (see Chapter 14, The To-Do Pane).

15.4.13. Choose a Legal Name

All artifact names in ArgoUML must use only letters, digits and underscore characters. This critic suggests an entity has not met this requirement.

15.4.14. Change an Artifact to a Non-Reserved Word

Suggestion that this artifact's name is the same as a reserved word in UML (or within one character of one), which is not permitted.

15.4.15. Choose a Better Operation Name

Suggestion that an operation has not followed the naming convention that operation names begin with lower case letters.

Caution
Following the Java and C++ convention most designers give their constructors the same name as the class, which begins with an upper case character. In ArgoUML, this will trigger this critic, unless the constructor is stereotyped ??create??.

It is important to remember that critics offer guidance, and are not always correct. ArgoUML lets you dismiss the resulting to-do items through the to-do pane (see Chapter 14, The To-Do Pane).

### 15.4.16. Choose a Better Attribute Name

Suggestion that an attribute has not followed the naming convention that attribute names begin with lower case letters.

### 15.4.17. Capitalize Class Name

Suggestion that a class has not followed the naming convention that classes begin with upper case letters.

**Note**

Although not triggering this critic, the same convention should apply to interfaces.

### 15.4.18. Revise Package Name

Suggestion that a package has not followed the naming convention of using lower case letters with periods used to indicated sub-packages.

### 15.5. Storage

Critics concerning attributes of classes.

The current version of ArgoUML has the following critics in this category.

### 15.5.1. Revise Attribute Names to Avoid Conflict

This critic is discussed under an earlier design issues category (see Section 15.4.2, “Revise Attribute Names to Avoid Conflict”).

### 15.5.2. Add Instance Variables to a Class

Suggestion that no instance variables have been specified for the given class. Such classes may be created to specify static attributes and methods, but by convention should then be given the stereotype ??utility??.

### 15.5.3. Add a Constructor to a Class

You have not yet defined a constructor for class `class`. Constructors initialize new instances such that their attributes have valid values. This class probably needs a constructor because not all of its attributes have initial values.
Defining good constructors is key to establishing class invariants, and class invariants are a powerful aid in writing solid code.

To fix this, add a constructor manually by clicking on class in the explorer and adding an operation using the context sensitive pop-up menu in the property tab, or select class where it appears on a class diagram and use the Add Operation tool.

In the UML 1.4 standard, a constructor is an operation with the stereotype ??create??. Although not strictly standard, ArgoUML will also accept ??Create?? as a stereotype for constructors.

By convention in Java and C++ a constructor has the same name as the class, is not static, and returns no value. ArgoUML will also accept any operation that follows these conventions as a constructor even if it is not stereotyped ??create??.

**Caution**

Operators are created in ArgoUML with a default return parameter (named return). You will need to remove this parameter to meet the Java/C++ convention.

15.5.4. Reduce Attributes on a Class

Suggestion that the class has too many attributes for a good design, and is at risk of becoming a design bottleneck.

The Wizard of this critic allows setting of the threshold, i.e. the maximum number of attributes allowed before this critic fires.

**Caution**

This number is not stored persistently, and there is no way to reduce it after it has been set higher, except by creating more attributes until the critic fires again. Restarting ArgoUML resets this number to its default: 7.

15.6. Planned Extensions

Critics concerning interfaces and subclasses.

**Note**

It is not clear why this category has the name “Planned Extensions”.

The current version of ArgoUML has three critics in this category.

15.6.1. Operations in Interfaces must be public

Suggestion that there is no point in having non-public operations in Interfaces, since they must be visible to be realized by a class.

15.6.2. Interfaces may only have operations

Suggestion that an interfaces has attributes defined. The UML standard defines interfaces to have operations.
Caution

ArgoUML does not allow you to add attributes to interfaces, so this should never occur in the ArgoUML model. It might trigger if a project has been loaded with XMI created by another tool.

15.6.3. Remove Reference to Specific Subclass

Suggestion that in a good design, a class should not reference its subclasses directly through attributes, operations or associations.

15.7. State Machines

Critics concerning state machines.

ArgoUML has the following critics in this category.

15.7.1. Reduce Transitions on <state>

Suggestion given state is involved in so many transitions it may be a maintenance bottleneck.

The Wizard of this critic allows setting of the threshold, i.e. the maximum number of transitions allowed before this critic fires.

Caution

This number is not stored persistently, and there is no way to reduce it after it has been set higher, except by creating more transition until the critic fires again. Restarting ArgoUML resets this number to its default: 10.

15.7.2. Reduce States in machine <machine>

Suggestion that the given state machine has so many states as to be confusing and should be simplified (perhaps by breaking into several machines, or using a hierarchy).

The Wizard of this critic allows setting of the threshold, i.e. the maximum number of states allowed before this critic fires.

Caution

This number is not stored persistently, and there is no way to reduce it after it has been set higher, except by creating more states until the critic fires again. Restarting ArgoUML resets this number to its default: 20.

15.7.3. Add Transitions to <state>

Suggestion that the given state requires both incoming and outgoing transitions.

15.7.4. Add Incoming Transitions to <artifact>
Suggestion that the given state requires incoming transitions.

15.7.5. Add Outgoing Transitions from <artifact>
Suggestion that the given state requires outgoing transitions.

15.7.6. Remove Extra Initial States
Suggestion that there is more than one initial state in the state machine or composite state, which is not permitted in UML.

15.7.7. Place an Initial State
Suggestion that there is no initial state in the state machine or composite state.

15.7.8. Add Trigger or Guard to Transition
Suggestion that a transition is missing either a trigger or guard, one at least of which is required for it to be taken.

15.7.9. Change Join Transitions
Suggestion that the join pseudostate has an invalid number of transitions. Normally there should be one outgoing and two or more incoming.

15.7.10. Change Fork Transitions
Suggestion that the fork pseudostate has an invalid number of transitions. Normally there should be one incoming and two or more outgoing.

15.7.11. Add Choice/Junction Transitions
Suggestion that the branch (choice or junction) pseudostate has an invalid number of transitions. Normally there should be at least one incoming transition and at least one outgoing transition.

15.7.12. Add Guard to Transition
Suggestion that the transition requires a guard.

Caution

It is not clear that this is a valid critic. It is perfectly acceptable to have a transition without a guard??the transition is always taken when the trigger is invoked.

15.7.13. Clean Up Diagram
This critic is discussed under an earlier design issues category (see Section 15.3.3, “Clean Up Diagram”).

15.7.14. Make Edge More Visible
Suggestion that an edge artifact such as an association or abstraction is so short it may be missed. Move the connected artifacts apart to make the edge more visible.

15.7.15. Composite Association End with Multiplicity > 1

An instance may not belong by composition to more than one composite instance. You must change the multiplicity at the composite end of the association to either 0..1 or 1..1 (1) for your model to make sense.

Remember that composition is the stronger aggregation kind and aggregation is the weaker. The problem can be compared to a model where a finger can be an integral part of several hands at the same time.

This is the second well-formedness rule on AssociationEnd in UML 1.4.

15.8. Design Patterns

Critics concerning design pattern usage in ArgoUML.

These relate to the use of patterns as described by the so called “Gang of Four”. ArgoUML also uses this category for critics associated with deployment and sequence diagrams. The current version of ArgoUML has the following critics in this category.

15.8.1. Consider using Singleton Pattern for <class>

The class has no non-static attributes nor any associations that are navigable away from instances of this class. This means that every instance of this class will be identical to every other instance, since there will be nothing about the instances that can differentiate them.

Under these circumstances you should consider making explicit that you have exactly one instance of this class, by using the singleton Pattern. Using the singleton pattern can save time and memory space. Within ArgoUML this can be done by using the ??singleton?? stereotype on this class.

If it is not your intent to have a single instance, you should define instance variables (i.e. non-static attributes) and/or outgoing associations that will represent differences between instances.

Having specified class as a singleton, you need to define the class so there can only be a single instance. This will complete the information representation part of your design. To achieve this you need to do the following.

1. You must define a static attribute (a class variable) holding the instance. This must therefore have class as its type.

2. You must have only private constructors so that new instances cannot be made by other code. The creation of the single instance could be through a suitable helper operation, which invokes this private constructor just once.

3. You must have at least one constructor to override the default constructor, so that the default constructor is not used to create multiple instances.

For the definition of a constructor under the UML 1.4 standard, and extensions to that definition accepted by ArgoUML see Section 15.5.3, “Add a Constructor to a Class”.

15.8.2. Singleton Stereotype Violated in <class>
This class is marked with the ??singleton?? stereotype, but it does not satisfy the constraints imposed on
singletons (ArgoUML will also accept ??Singleton?? stereotype as defining a singleton). A singleton
class can have at most one instance. This means that the class must meet the design criteria for a
singleton (see Section 15.8.1, “Consider using Singleton Pattern for <class>”).

Whenever you mark a class with a stereotype, the class should satisfy all constraints of the stereotype.
This is an important part of making a self-consistent and understandable design. Using the singleton pat-
ttern can save time and memory space.

If you no longer want this class to be a singleton, remove the ??singleton?? stereotype by clicking on the
class and selecting the blank selection on the stereotype drop-down within the properties tab.

To apply the singleton pattern you should follow the directions in Section 15.8.1, “Consider using
Singleton Pattern for <class>”.

15.8.3. Nodes normally have no enclosers

A suggestion that nodes should not be drawn inside other artifacts on the deployment diagram, since
they represent an autonomous physical object.

15.8.4. NodeInstances normally have no enclosers

A suggestion that node instances should not be drawn inside other artifacts on the deployment diagram,
since they represent an autonomous physical object.

15.8.5. Components normally are inside nodes

A suggestion that components represent the logical entities within physical nodes, and so should be
drawn within a node, where nodes are shown on the deployment diagram.

15.8.6. ComponentInstances normally are inside nodes

A suggestion that component instances represent the logical entities within physical nodes, and so
should be drawn within a node instance, where node instances are shown on the deployment diagram.

15.8.7. Classes normally are inside components

A suggestion that classes, as artifacts making up components, should be drawn within components on
the deployment diagram.

15.8.8. Interfaces normally are inside components

A suggestion that interfaces, as artifacts making up components, should be drawn within components on
the deployment diagram.

15.8.9. Objects normally are inside components

A suggestion that objects, as instances of artifacts making up components, should be drawn within com-
ponents or component instances on the deployment diagram.

15.8.10. LinkEnds have not the same locations

A suggestion that a link (e.g. association) connecting objects on a deployment diagram has one end in a
component and the other in a component instance (since objects can be in either). This makes no sense.

15.8.11. **Set classifier (Deployment Diagram)**

Suggestion that there is an instance (object) without an associated classifier (class, datatype) on a deployment diagram.

15.8.12. **Missing return-actions**

Suggestion that a sequence diagram has a send or call action without a corresponding return action.

15.8.13. **Missing call(send)-action**

Suggestion that a sequence diagram has a return action, but no preceding call or send action.

15.8.14. **No Stimuli on these links**

Suggestion that a sequence diagram has a link connecting objects without an associated stimulus (without which the link is meaningless).

**Warning**

Triggering this critic indicates a serious problem, since ArgoUML provides no mechanism for creating a link without a stimulus. It probably indicates that the diagram was created by loading a corrupt project, with an XMI file describing a link without a stimulus, possibly created by a tool other than ArgoUML.

15.8.15. **Set Classifier (Sequence Diagram)**

Suggestion that there is an object without an associated classifier (class, datatype) on a sequence diagram.

15.8.16. **Wrong position of these stimuli**

Suggestion that the initiation of send/call-return message exchanges in a sequence diagram does not properly initiate from left to right.

15.9. **Relationships**

Critics concerning associations in ArgoUML.

The current version of ArgoUML has the following critics in this category.

15.9.1. **Circular Association**

Suggestion that an association class has a role that refers back directly to itself, which is not permitted.

**Warning**

This critic is meaningless in the V0.14 version of ArgoUML which does not support association classes.
15.9.2. Make <association> Navigable

Suggestion that the association referred to is not navigable in either direction. This is permitted in the UML standard, but has no obvious meaning in any practical design.

15.9.3. Remove Navigation from Interface via <association>

Associations involving an interface can be not be navigable in the direction from the interface. This is because interfaces contain only operation declarations and cannot hold pointers to other objects.

This part of the design should be changed before you can generate code from this design. If you do generate code before fixing this problem, the code will not match the design.

To fix this, select the association and use the Properties tab to select in turn each association end that is not connected to the interface. Uncheck Navigable for each of these ends.

The association should then appear with a stick arrowhead pointed towards the interface.

When an association between a class and interface is created in ArgoUML, it is by default navigable only from the class to the interface. However, ArgoUML does not prevent to change the navigability afterwards into a wrong situation. Which will cause this critic to be triggered.

15.9.4. Add Associations to <artifact>

Suggestion that the specified artifact (actor, use case or class) has no associations connecting it to other artifacts. This is required for the artifact to be useful in a design.

15.9.5. Remove Reference to Specific Subclass

This critic is discussed under an earlier design issues category (see Section 15.6.3, “Remove Reference to Specific Subclass”).

15.9.6. Reduce Associations on <artifact>

Suggestion that the given artifact (actor, use case, class or interface) has so many associations it may be a maintenance bottleneck.

The Wizard of this critic allows setting of the threshold, i.e. the maximum number of associations allowed before this critic fires.

Caution

This number is not stored persistently, and there is no way to reduce it after it has been set higher, except by creating more associations until the critic fires again. Restarting ArgoUML resets this number to its default: 7.

15.9.7. Make Edge More Visible

This critic is discussed under an earlier design issues category (see Section 15.7.14, “Make Edge More Visible”).
15.10. Instantiation

Critics concerning instantiation of classifiers in ArgoUML.

The current version of ArgoUML has no critics in this category.

15.11. Modularity

Critics concerning modular development in ArgoUML.

The current version of ArgoUML has the following critics in this category.

15.11.1. Classifier not in Namespace of its Association

One of the well-formedness rules in UML 1.4 for associations, is that all the classifiers attached to the ends of the association should belong to the same namespace as the association.

If this were not the case, there would be no naming, by which each end could refer to all the others.

This critic is triggered when an association does not meet this criterion. The solution is to delete the association, and recreate it on a diagram, whose namespace includes those of all the attached classifiers.

Caution

In the current implementation of ArgoUML, this critic does not handle hierarchical namespaces. As a consequence, it will trigger for associations where the immediate namespaces of the attached classifiers is different, even though they are part of the same namespace hierarchy.

15.11.2. Add Elements to Package <package>

Suggestion that the specified package has no content. Good design suggests packages are created to put things in.

Note

This will always trigger when you first create a package, since you cannot create one that is not empty!

15.12. Expected Usage

Critics concerning generally accepted good practice in ArgoUML.

The current version of ArgoUML has one critic in this category.

15.12.1. Clean Up Diagram

This critic is discussed under an earlier design issues category (see Section 15.3.3, “Clean Up Diagram”).

15.13. Methods
Critics concerning operations in ArgoUML.

The current version of ArgoUML has the following critics in this category.

15.13.1. Change Names or Signatures in <artifact>

This critic is discussed under an earlier design issues category (see Section 15.4.3, “Change Names or Signatures in an Artifact”).

15.13.2. Class Must be Abstract

Suggestion that a class that inherits or defines abstract operations must be marked abstract.

15.13.3. Add Operations to <class>

Suggestion that the specified class has no operations defined. This is required for the class to be useful in a design.

15.13.4. Reduce Operations on <artifact>

Suggestion that the artifact (class or interface) has too many operations for a good design, and is at risk of becoming a design bottleneck.

The Wizard of this critic allows setting of the threshold, i.e. the maximum number of operations allowed before this critic fires.

Caution

This number is not stored persistently, and there is no way to reduce it after it has been set higher, except by creating more operations until the critic fires again. Restarting ArgoUML resets this number to its default: 20.

15.14. Code Generation

Critics concerning code generation in ArgoUML.

The current version of ArgoUML has one critic in this category.

15.14.1. Change Multiple Inheritance to interfaces

Suggestion that a class has multiple generalizations, which is permitted by UML, but cannot be generated into Java code, because Java does not support multiple inheritance.

15.15. Stereotypes

Critics concerning stereotypes in ArgoUML.

The current version of ArgoUML has no critics in this category.

15.16. Inheritance
Critics concerning generalization and specialization in ArgoUML.

The current version of ArgoUML has the following critics in this category.

15.16.1. Revise Attribute Names to Avoid Conflict

This critic is discussed under an earlier design issues category (see Section 15.4.2, “Revise Attribute Names to Avoid Conflict”).

15.16.2. Remove <class>’s Circular Inheritance

Suggestion that a class inherits from itself, through a chain of generalizations, which is not permitted.

Caution

This critic is marked inactive by default in the current release of ArgoUML (the only one so marked). It will not trigger unless made active.

15.16.3. Class Must be Abstract

This critic is discussed under an earlier design issues category (see Section 15.13.2, “Class Must be Abstract”).

15.16.4. Remove final keyword or remove subclasses

Suggestion that a class that is final has specializations, which is not permitted in UML.

15.16.5. Illegal Generalization

Suggestion that there is a generalization between artifacts of different UML metaclasses, which is not permitted.

Caution

It is not clear that such a generalization can be created within ArgoUML. It probably indicates that the diagram was created by loading a corrupt project, with an XMI file describing such a generalization, possibly created by a tool other than ArgoUML.

15.16.6. Remove Unneeded Realizes from <class>

Suggestion that the specified class has a realization relationship both directly and indirectly to the same interface (by realization from two interfaces, one of which is a generalization of the other for example). Good design deprecates such duplication.

15.16.7. Define Concrete (Sub)Class

Suggestion that a class is abstract with no concrete subclasses, and so can never be realized.

15.16.8. Define Class to Implement <interface>

Suggestion that the interface referred to has no influence on the running system, since it is never imple-
mented by a class.

15.16.9. Change Multiple Inheritance to interfaces

This critic is discussed under an earlier design issues category (see Section 15.14.1, “Change Multiple Inheritance to interfaces”).

15.16.10. Make Edge More Visible

This critic is discussed under an earlier design issues category (see Section 15.7.14, “Make Edge More Visible”).

15.17. Containment

Critics concerning containment in ArgoUML, that is where one artifact forms a component part of another.

The current version of ArgoUML has the following critics in this category.

15.17.1. Remove Circular Composition

Suggestion that there is a series of composition relationships (associations with black diamonds) that form a cycle, which is not permitted.

15.17.2. Duplicate Parameter Name

Suggestion that a parameter list to an operation or event has two or more parameters with the same name, which is not permitted.

15.17.3. Two Aggregate Ends (Roles) in Binary Association

Only one end (role) of a binary association can be aggregate or composite. This a well-formedness rule of the UML 1.4 standard.

Aggregation and composition are used to indicate whole-part relationships, and by definition, the “part” end cannot be aggregate.

To fix this, identify the “part” end of the association, and use the critic wizard (the Next> button, or manually set its aggregation to none using the button 2 pop-up menu or the property sheet.

Composition (more correctly called composite aggregation) is used where there is a whole-part relationship that is one-to-one or one-to-many, and the lifetime of the part is inextricably tied to the lifetime of the whole. Instances of the whole will have responsibility for creating and destroying instances of the associated part. This also means that a class can only be a part in one composite aggregation.

An example of a composite aggregation might be a database of cars and their wheels. This is a one-to-four relationship, and the database entry for a wheel is associated with its car. When the car ceases to exist in the database, so do its wheels.

Aggregation (more correctly called shared aggregation) is used where there is a whole-part relationship, that does not meet the criteria for a composite aggregation. An example might be a database of university courses and the students that attend them. There is a whole-part relationship between courses and
students. However there is no lifetime relationship between students and course (a student continues to exist even after a course is finished) and the relationship is many-to-many.

15.17.4. Aggregate End (Role) in 3-way (or More) Association

Three-way (or more) associations can not have aggregate ends (roles). This a well-formedness rule of the UML 1.4 standard.

Aggregation and composition are used to indicate whole-part relationships, and by definition can only apply to binary associations between artifacts.

To fix this, manually select the association, and set the aggregation of each of its ends (roles) to none using the button 2 pop-up menu or the property sheet.

15.17.5. Wrap DataType

This critic is discussed under an earlier design issues category (see Section 15.3.1, “Wrap DataType”).
Part 3. Model Reference
Chapter 16. Top Level Artifact Reference

16.1. Introduction

This chapter describes each artifact that can be created within ArgoUML. The chapter covers top-level “general” artifacts. The following chapters (see Chapter 17, Use Case Diagram Artifact Reference through Chapter 23, Deployment Diagram Artifact Reference) cover each of the ArgoUML diagrams.

There is a close relationship between this material and the properties tab of the details pane (see Section 13.3, “Properties Tab”). That section covers properties in general, in this chapter they are linked to specific artifacts.

16.2. The Model

The model is the top level artifact within ArgoUML. In the UML meta-model it is a sub-class of package. In many respects within ArgoUML it behaves similarly to a package (see Section 18.2, “Package”).

Note

ArgoUML is restricted to one model within the tool.

Standard data types, classes and packages are loaded (the default, see Chapter 24, Built In DataTypes, Classes, Interfaces and Stereotypes) as sub-packages of the model. These sub-packages are not initially present in the model but are added to the model when used.

16.2.1. Model Details Tabs

The details tabs that are active for the model are as follows.

ToDoItem
   Standard tab.

Properties
   See Section 16.2.2, “Model Property Toolbar” and Section 16.2.3, “Property Fields For The Model” below.

Documentation
   Standard tab. See Section 13.4, “Documentation Tab”.

Stereotype
   Standard tab. This contains a list of the stereotypes applied to this model, and a list of available stereotypes that may be applied to the model.

Tagged Values
   Standard tab. In the UML meta-model, Model has the following standard tagged values defined.
   • derived (from the superclass, ModelElement).

   Values true, meaning the class is redundant ?? it can be formally derived from other elements, or false meaning it cannot.
Derived models have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

### 16.2.2. Model Property Toolbar

**Go up**
Navigate up through the composition structure of the model.

Since the model is the top package nothing can happen, and this button is always downlighted.

**New Package**
This creates a new Package (see Section 18.2, “Package”) within the model (which appears on no diagram), navigating immediately to the properties tab for that package.

**Tip**
While it can make sense to create Packages of the model this way, it is usually a lot clearer to create them within diagrams where you want them.

**New DataType**
This creates a new DataType (see Section 16.3, “Datatype”) within the model (which appears on no diagram), navigating immediately to the properties tab for that DataType.

**New Enumeration**
This creates a new Enumeration (see Section 16.4, “Enumeration”) within the model (which appears on no diagram), navigating immediately to the properties tab for that Enumeration.

**New Stereotype**
This creates a new Stereotype (see Section 16.5, “Stereotype”) within the model, navigating immediately to the properties tab for that stereotype.

**Delete**
This tool is always downlighted, since it is meaningless to delete the model!

### 16.2.3. Property Fields For The Model

**Name**
Text box. The name of the model. The name of a model, like all packages, is by convention all lower case.

**Note**
The default name supplied to a new model by ArgoUML, `untitledModel`, is thus erroneous and guarantees that ArgoUML always starts up with at least one problem being reported by the design critics.
Stereotype

Drop down selector. Model is provided by default with the UML standard stereotypes for model (systemModel and metamodel) and package (facade, framework, stub).

Stereotyping models is a useful thing, although it is of limited value in ArgoUML where you have only a single model.

Navigate Stereotype

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace

Text box. Records the namespace for the model. This is the package hierarchy. However since the model is at the top of the hierarchy in ArgoUML, this box is always empty.

Visibility

Radio box, with entries public, private, protected, and package.

Records the visibility for the model. Since ArgoUML only permits one model, this has no meaningful use.

Modifiers

Check box, with entries Abstract, Leaf and Root.

• abstract is used to declare that this model cannot be instantiated, but must always be specialized.

The meaning of abstract applied to a model is not that clear. It might mean that the model contains interfaces or abstract classes without realizations. Since ArgoUML only permits one model, this is not a meaningful box to check.

• Leaf indicates that this model can have no further subpackages, while root indicates it is the top level model.

Within ArgoUML root only meaningfully applies to the Model, since all packages sit within the model. In the absence of the topLevel stereotype, this could be used to emphasize that the Model is at the top level.

Generalizations

Text area. Lists any model that generalizes this model.

Note

Since there is only one model in ArgoUML there is no sensible specialization or generalization that could be created.

Specializations

Text box. Lists any specialized model (i.e. for which this model is a generalization.

Note

Since there is only one model in ArgoUML there is no sensible specialization or generalization that could be created.
Owned Elements

Text area. A listing of the top level packages, classes, interfaces, datatypes, actors, use cases, associations, generalizations, and stereotypes within the model.

Button 1 double click on any of the artifacts yields navigating to that artifact.

16.3. Datatype

Datatypes can be thought of as simple classes. They have no attributes, and any operations on them must have no side-effects. A useful analogy is primitive datatypes in a language like Java. The integer “3” stands on its own—it has no inner structure. There are operations (for example addition) on the integers, but when I perform $3 + 4$ the result is a new number, “3” and “4” are unchanged by the exercise.

Within UML 1.3, \texttt{DataType} is a sub-class of the \texttt{Classifier} metaclass. It embraces the predefined primitive types (\texttt{byte}, \texttt{char}, \texttt{double}, \texttt{float}, \texttt{int}, \texttt{long} and \texttt{short}), the predefined enumeration, \texttt{boolean} and user defined \texttt{enumeration types}.

\textbf{Note}

Also \texttt{void} is implemented as a datatype within ArgoUML

Within ArgoUML new datatypes may be created using the \texttt{New datatype} button on the property tabs of the model and packages (in which case the new datatype is restricted in scope to the package), as well as the properties tab for datatype.

\textbf{Note}

UML 1.3 allows user defined datatypes to be placed on class diagrams. This is not permitted in ArgoUML.

16.3.1. Datatype Details Tabs

The details tabs that are active for datatypes are as follows.

\texttt{ToDoItem}

Standard tab.

\texttt{Properties}

See Section 16.3.2, “Datatype Property Toolbar” and Section 16.3.3, “Property Fields For Datatype” below.

\texttt{Documentation}

Standard tab. See Section 13.4, “Documentation Tab”.

\texttt{Source}

Standard tab. Unused. One would expect a class declaration for the new datatype to support code generation.

\texttt{Tagged Values}
Standard tab. In the UML metamodel, **datatype** has the following standard tagged values defined.

- **persistence** (from the superclass, **Classifier**). Values **transitory**, indicating state is destroyed when an instance is destroyed or **persistent**, marking state is preserved when an instance is destroyed.

  **Tip**

  Since user defined datatypes are enumerations, they have no state to preserve, and the value of this tagged value is irrelevant.

- **semantics** (from the superclass, **Classifier**). The value is a specification of the semantics of the datatype.

- **derived** (from the superclass, **ModelElement**). Values **true**, meaning the class is redundant??it can be formally derived from other elements, or **false** meaning it cannot.

  **Tip**

  While formally available, a derived datatype does not have an obvious value, and so datatypes should always be marked with **derived=false**.

### 16.3.2. Datatype Property Toolbar

**Go up**

Navigate up through the package structure.

**New datatype**

This creates a new datatype (see Section 18.5, “Class”) within the same package as the current datatype.

  **Tip**

  While it can make sense to create datatypes this way, it can be clearer to create them within the package or model where you want them.

**New enumeration literal**

This creates a new enumeration literal within the datatype, navigating immediately to the properties tab for that literal.

  **Caution**

  ArgoUML does not actually have a separate concept of a literal. The navigation will navigate to the property sheet for an attribute of a class (see Section 18.6, “Attribute”). When defining a literal, all that matters is its name. Other parts of the attribute property sheet should be ignored. Also the name of the literal must obey the rules for an Attribute or a critic will fire.

**New Operation**

This creates a new operation within the datatype, navigating immediately to the properties tab for
that operation.

**New Stereotype**

This creates a new Stereotype (see Section 16.5, “Stereotype”) within the same package as the datatype, navigating immediately to the properties tab for that stereotype.

**Delete**

This deletes the datatype from the model.

### 16.3.3. Property Fields For Datatype

**Name**

Text box. The name of the datatype. The primitive datatypes all have lower case names, but there is no formal convention.

**Note**

The default name supplied for a newly created datatype is the empty string “”. Datatypes with empty string names will appear with the name (anon Datatype) in the explorer.

**Stereotype**

Drop down selector. Stereotype is provided by default with the UML standard stereotypes for classifier (metaclass, powertype, process, thread and utility).

**Tip**

The stereotype enumeration should always be used for any created enumeration datatypes.

**Caution**

In ArgoUML version 0.18 the stereotype enumeration must be created before it can be used. However, by creating an Enumeration Literal, the stereotype enumeration is created automatically.

**Navigate Stereotype**

Icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Namespace**

Drop down selector. Allows changing the namespace for the datatype. This is the package hierarchy.

**Modifiers**

Check box, with entries Abstract, Leaf and Root.

- **Abstract** is used to declare that this datatype cannot be instantiated, but must always be specialized.
Note

ArgoUML provides no mechanism for specializing datatypes, so this check box is of little use.

- Leaf indicates that this datatype can have no further sub-types, while Root indicates it is a top level datatype.

Tip

In the absence of specialization of datatypes within ArgoUML these have little value. In effect all datatypes are both Root and Final

Visibility

Radio box, with entries public, private, protected, and package.

Records the visibility for the Datatype.

Client Dependencies

Text area. Lists any elements that depend on this datatype.

Caution

It is not clear that dependencies between datatypes makes much sense.

Supplier Dependencies

Text area. Lists any elements that this datatype depends on.

Caution

It is not clear that dependencies between datatypes makes much sense.

Generalizations

Text area. Lists any datatype that generalizes this datatype.

Caution

It is not clear that generalizing datatypes makes much sense.

Specializations

Text box. Lists any specialized datatype (i.e. for which this datatype is a generalization.

Caution

It is not clear that specializing datatypes makes much sense.

Operations

Text area. Lists all the operations defined on this datatype. Button 1 double click navigates to the selected operation. button 2 click brings up a pop up menu with two entries.
• Move Up. Only available where there are two or more operations, and the operation selected is not at the top. It is moved up one.

• Move Down. Only available where there are two or more operations listed, and the operation selected is not at the bottom. It is moved down one.

See Section 18.7, “Operation” for details of operations.

Caution

ArgoUML treats all operations as equivalent. Any operations created here will use the same mechanism as operations for classes. Remember that operations on datatypes must have no side effects (they are read-only). This means the query modifier must be checked for all operations.

Literals

Text area. Lists all the enumeration literals defined for this datatype. Button 1 double click navigates to the selected literal, button 2 click brings up a pop up menu with two entries.

• Move Up. Only available where there are two or more literals, and the literal selected is not at the top. It is moved up one.

• Move Down. Only available where there are two or more literals listed, and the literal selected is not at the bottom. It is moved down one.

Caution

ArgoUML does not actually have a separate concept of a literal. The navigations listed above will all navigate to a property sheet equal to an attribute of a class (see Section 18.6, “Attribute”). When defining a literal, all that matters is its name. Other parts of the attribute property sheet should be ignored.

16.4. Enumeration

Enumeration can be thought of as simple classes. They have no attributes, and any operations on them must have no side-effects. A useful analogy is primitive datatypes in a language like Java. The boolean “true” stands on its own—it has no inner structure. There are operations (for example logical xor) on the booleans, but when I perform true xor true the result is a new boolean, and the original 2 booleans “true” are unchanged by the exercise.

Within UML 1.4, Enumeration is a sub-class of the DataType metaclass.

The big difference with other DataTypes, is that an Enumeration has EnumerationLiterals. E.g. the Enumeration “boolean” is defined as having 2 EnumerationLiterals, “true” and “false”.

Within ArgoUML new enumerations may be created using the New Enumeration button on the property tabs of the model and packages (in which case the new enumeration is restricted in scope to the package), as well as the properties tab for datatype and enumeration.

Note

UML 1.4 allows user defined datatypes to be placed on class diagrams. This is not yet possible in ArgoUML.
16.4.1. Enumeration Details Tabs

The details tabs that are active for enumerations are as follows.

**ToDoItem**
Standard tab.

**Properties**
See Section 16.4.2, “Enumeration Property Toolbar” and Section 16.4.3, “Property Fields For Enumeration” below.

**Documentation**
Standard tab. See Section 13.4, “Documentation Tab”.

**Source**
Standard tab.

**Stereotype**
Standard tab. The UML metamodel has the following stereotypes defined by default for a Classifier, which also apply to an Enumeration:

- metaclass (from the superclass, Classifier).
- powertype (from the superclass, Classifier).
- process (from the superclass, Classifier).
- thread (from the superclass, Classifier).
- utility (from the superclass, Classifier).

**Tagged Values**
Standard tab. In the UML metamodel, Enumeration has no standard tagged values defined.

16.4.2. Enumeration Property Toolbar

**Go up**
Navigate up through the composition structure.

**New datatype**
This creates a new datatype (see Section 18.5, “Class”) within the same package as the current enumeration.

**New enumeration literal**
This creates a new enumeration literal within the enumeration, navigating immediately to the properties tab for that literal.

**New Operation**
This creates a new operation within the enumeration, navigating immediately to the properties tab for that operation.

**New Stereotype**
This creates a new Stereotype (see Section 16.5, “Stereotype”) within the same package as the enum-
meration, navigating immediately to the properties tab for that stereotype.

**Delete from Model**
This deletes the datatype from the model.

### 16.4.3. Property Fields For Enumeration

**Name**
Text box. The name of the enumeration. The primitive enumerations all have lower case names, but there is no formal convention.

**Note**
The default name supplied for a newly created datatype is the empty string "". Enumerations with empty string names will appear with the name (anon Enumeration) in the explorer.

**Namespace**
Drop down selector. Allows changing the namespace for the enumeration. This is the composition hierarchy.

**Modifiers**
Check box, with entries Abstract, Leaf and Root.

- **Abstract** is used to declare that this enumeration cannot be instantiated, but must always be specialized.

  **Note**
  ArgoUML provides no mechanism for specializing enumerations, so this check box is of little use.

- **Leaf** indicates that this enumeration can have no further sub-types, while **Root** indicates it is a top level enumeration.

  **Tip**
  In the absence of specialization of enumerations within ArgoUML these have little value. In effect all enumerations are both **Root** and **Final**.

**Visibility**
Radio box, with entries public, private, protected, and package.
Records the visibility for the Enumeration.

**Client Dependencies**
Text area. Lists any elements that depend on this enumeration.

**Caution**
It is not clear that defining dependencies between enumerations makes much sense.

**Supplier Dependencies**
Text area. Lists any elements that this enumeration depends on.

**Caution**
It is not clear that defining dependencies between enumeration makes much sense.

**Generalizations**
Text area. Lists any enumeration that generalizes this enumeration.

**Specializations**
Text box. Lists any specialized enumerations (i.e. for which this enumeration is a generalization.

**Operations**
Text area. Lists all the operations defined on this enumeration. Button 1 double click navigates to the selected operation. button 2 click brings up a pop up menu with two entries.

- **Move Up.** Only available where there are two or more operations, and the operation selected is not at the top. It is moved up one.

- **Move Down.** Only available where there are two or more operations listed, and the operation selected is not at the bottom. It is moved down one.

See Section 18.7, “Operation” for details of operations.

**Caution**
ArgoUML treats all operations as equivalent. Any operations created here will use the same mechanism as operations for classes. Remember that operations on enumerations must have no side effects (they are read-only). This means the query modifier must be checked for all operations.

**Literals**
Text area. Lists all the enumeration literals defined for this enumeration. Button 1 double click navigates to the selected literal, button 2 click brings up a pop up menu with two entries.

- **Move Up.** Only available where there are two or more literals, and the literal selected is not at the top. It is moved up one.

- **Move Down.** Only available where there are two or more literals listed, and the literal selected is not at the bottom. It is moved down one.

**16.5. Stereotype**
Stereotypes are the main extension mechanism of UML, providing a way to derive specializations of the standard metaclasses. Stereotype is a sub-class of GeneralizableElement in the UML metamodel. Stereotypes are supplemented by constraints and tagged values.

New stereotypes are added from the property tab of almost any artifact. Properties of existing stereotypes can be reached by selecting the property tab for any artifact with that stereotype and using the
navstereo button ( ) within the property tab.

16.5.1. Stereotype Details Tabs

The details tabs that are active for stereotypes are as follows.

ToDoItem
Standard tab.

Properties
See Section 16.5.2, “Stereotype Property Toolbar” and Section 16.5.3, “Property Fields for Stereotype” below.

Documentation
Standard tab. See Section 13.4, “Documentation Tab”.

Source
Standard tab. This contains the representation of the stereotype on diagrams (its name between ?? and ??).

**Warning**

You can edit this entry, but it has no effect and when you return to the entry it will be restored to its original value.

Tagged Values
Standard tab. In the UML metamodel, Stereotype has the following standard tagged values defined.

- derived (from the superclass, ModelElement). Values true, meaning the class is redundant??it can be formally derived from other elements, or false meaning it cannot.

**Note**

This indicates any element with this stereotype has the derived tag set accordingly.

**Caution**

Tagged values for a stereotype are rather different to those for elements in the UML core architecture, in that they apply to all artifacts to which the stereotype is applied, *not* just the stereotype itself.

16.5.2. Stereotype Property Toolbar

**Go up**

Navigate up through the package structure of the model.

**Add stereotype**

This creates a new stereotype (see Section 16.5, “Stereotype”) within the model (which appears on no diagram), navigating immediately to the properties tab for that stereotype.
16.5.3. Property Fields For Stereotype

Name

Text box. The name of the stereotype. There is no convention for naming stereotypes, beyond starting them with a lower case letter. Even the standard UML stereotypes vary between all lower case (e.g. metamodel), bumpy caps (e.g. systemModel) and space separated (e.g. object model).

Note

ArgoUML does not enforce any naming convention for stereotypes

Base Class

Drop down selector. Any stereotype must be derived from one of the metaclasses in the UML metamodel Abstraction, Actor, Association, AssociationEnd, Attribute, BehavioralFeature, CallEvent, Class, Classifier, Collaboration, Comment, Component, Constraint, DataType, Exception, Flow, Generalization, Interface, Link, Model, ModelElement, Node, NodeInstance, ObjectFlowState, Operation, Package, Permission, Signal, Subsystem and Usage) or the artifact classes that derive from them. The stereotype will then be available to artifacts that derive from that same metaclass or that artifact.

Namespace

Drop down selector. Records the namespace for the stereotype. This is the package hierarchy.

Modifiers

Check box, with entries Abstract, Leaf and Root.

- **Abstract** is used to declare that artifacts that use this stereotype cannot be instantiated, but must always be specialized.
- **Leaf** indicates that artifacts that use this stereotype can have no further sub-types, while **Root** indicates it is a top level artifact.

Caution

Remember that these modifiers apply to the artifacts using the stereotype, not just the stereotype.

Warning

ArgoUML neither imposes, nor checks that artifacts using a stereotype adopt the stereotype's modifiers.

Generalizations

Text area. Lists any stereotype that generalizes this stereotype.
Caution

It is not clear that generalizing stereotypes makes much sense.

Specializations

Text box. Lists any specialized stereotype (i.e. for which this stereotype is a generalization.

Caution

It is not clear that specializing stereotypes makes much sense.

16.6. Diagram

The UML standard specifies eight principal diagrams, all of which are supported by ArgoUML.

• Use case diagram. Used to capture and analyse the requirements for any OOA&D project. See Chapter 17, Use Case Diagram Artifact Reference for details of the ArgoUML use case diagram and the artifacts it supports.

• Class diagram. This diagram captures the static structure of the system being designed, showing the classes, interfaces and datatypes and how they are related. Variants of this diagram are used to show package structures within a system (the package diagram) and the relationships between particular instances (the object diagram).

The ArgoUML class diagram provides support for class and package diagrams. See Chapter 18, Class Diagram Artifact Reference for details of the artifacts it supports. The object diagram is supported on the Deployment diagram.

• Behavior diagrams. There are four such diagrams (or strictly speaking, five, since the use case diagram is a type of behavior diagram), which show the dynamic behavior of the system at all levels.

• Statechart diagram. Used to show the dynamic behavior of a single object (class instance). This diagram is of particular use in systems using complex communication protocols, such as in telecommunications. See Chapter 20, Statechart Diagram Artifact Reference for details of the ArgoUML statechart diagram and the artifacts it supports.

• Activity diagram. Used to show the dynamic behavior of groups of objects (class instance). This diagram is an alternative to the statechart diagram, and is better suited to systems with a great deal of user interaction. See Chapter 22, Activity Diagram Artifact Reference for details of the ArgoUML activity diagram and the artifacts it supports.

• Interaction diagrams. There are two diagrams in this category, used to show the dynamic interaction between objects (class instances) in the system.

• Sequence diagram. Shows the interactions (typically messages or procedure calls) between instances of classes (objects) and actors against a timeline. Particularly useful where the timing relationships between interactions are important. See Chapter 19, Sequence Diagram Artifact Reference for details of the ArgoUML sequence diagram and the artifacts it supports.

• Collaboration diagram. Shows the interactions (typically messages or procedure calls) between instances of classes (objects) and actors against the structural relationships between those instances. Particularly suitable where it is useful to relate interactions to the static structure of the system. See Chapter 21, Collaboration Diagram Artifact Reference for details of the ArgoUML
collaboration diagram and the artifacts it supports.

- **Implementation diagrams.** UML defines two implementation diagrams to show the relationship between the software components that make up a system (the component diagram) and the relationship between the software and the hardware on which it is deployed at run-time (the deployment diagram).

The ArgoUML deployment diagram provides support for both component and deployment diagrams, and additionally for object diagrams. See Chapter 23, *Deployment Diagram Artifact Reference* for details of the diagram and the artifacts it supports.

Diagrams are created using the *Create* drop down menu (see Section 10.6, “The Create Menu”), or with the tools on the toolbar (see Section 9.4, “Create operations”).

**Note**

ArgoUML uses its deployment diagram to create the UML 1.4 component, deployment and object diagrams.

**Caution**

Statechart and activity diagrams are associated with a particular class or operation (or the latter also with a package), and can only be created when this modelelement has been selected.

**Warning**

In ArgoUML version 0.20, the UML 1.4 object diagram as a variant of the class diagram is not directly supported. However, it is possible to create simple object diagrams within the ArgoUML deployment diagram.

### 16.6.1. Diagram Details Tabs

The details tabs that are active for diagrams are as follows.

- **ToDoItem**
  - Standard tab.

- **Properties**
  - See Section 16.6.3, “Property Fields For Diagram” below.

### 16.6.2. Diagram Property Toolbar

- **Go up**
  - Navigate up through the package structure of the model.

- **Delete**
  - This deletes the diagram from the model. As a consequence, in case of a statechart diagram or an
activity diagram, all contained elements are deleted, too.

16.6.3. Property Fields For Diagram

Name

The name of the diagram. There are no conventions for naming diagrams. By default, ArgoUML uses the (space separated) diagram name and a sequence number, thus Use Case Diagram 1.

Tip

This name is used to generate a filename when activating the “Save Graphics...” menu-item.
Chapter 17. Use Case Diagram Artifact Reference

17.1. Introduction

This chapter describes each artifact that can be created within a use case diagram. Note that some sub-artifacts of artifacts on the diagram may not actually themselves appear on the diagram.

There is a close relationship between this material and the properties tab of the details pane (see Section 13.3, “Properties Tab”). That section covers properties in general, in this chapter they are linked to specific artifacts.

Figure 17.1, “Possible artifacts on a use case diagram.” shows a use case diagram with all possible artifacts displayed.

Figure 17.1. Possible artifacts on a use case diagram.

17.1.1. ArgoUML Limitations Concerning Use Case Diagrams

Use case diagrams are now well supported within ArgoUML. There still are some minor limitations though. One is that extension points may be shown in a separate compartment on the use case, but this is not retained after saving and reloading.

Note

Earlier versions of ArgoUML (0.9 and earlier) implemented extend and include relationships by using a stereotyped dependency relationship. Although such diagrams will show correctly on the diagram, they will not link correctly to the use cases, and should be replaced by proper extend and include relationships using the current system.

17.2. Actor

An actor represents any external entity (human or machine) that interacts with the system, providing input, receiving output, or both.

Within the UML metamodel, actor is a sub-class of classifier.

The actor is represented by a “stick man” figure on the diagram (see Figure 17.1, “Possible artifacts on a use case diagram.”).

17.2.1. Actor Details Tabs

The details tabs that are active for actors are as follows.

ToDoItem
Standard tab.

**Properties**

See Section 17.2.2, “Actor Property Toolbar” and Section 17.2.3, “Property Fields For Actor” below.

**Documentation**

Standard tab. See Section 13.4, “Documentation Tab”.

**Presentation**

Standard tab. The fill color is used for the stick man’s head.

**Source**

Standard tab. Usually, no code is provided for an actor, since it is external to the system.

**Note**

The source tab content can be changed, but the changes are not retained.

**Constraints**

Standard tab. ArgoUML only supports constraints on Classes and Features (Attributes, Operations, Receptions, and Methods), so this tab is grayed out.

**Tagged Values**

Standard tab. In the UML metamodel, *Actor* has the following standard tagged values defined.

- **persistence** (from the superclass, *Classifier*). Values *transitory*, indicating state is destroyed when an instance is destroyed or *persistent*, marking state is preserved when an instance is destroyed.

**Tip**

Actors sit outside the system, and so their internal behavior is of little concern, and this tagged value is best ignored.

- **semantics** (from the superclass, *Classifier*). The value is a specification of the semantics of the actor.

- **derived** (from the superclass, *ModelElement*). Values *true* meaning the actor is redundant???, it can be formally derived from other elements, or *false* meaning it cannot.

**Note**

Derived actors have limited value, since they sit outside the system being designed. They may have their value in analysis to introduce useful names or concepts.

**Checklist**

Standard tab for a Classifier.

### 17.2.2. Actor Property Toolbar

**Go up**

Navigate up through the package structure of the model.
Add Actor

This creates a new actor within the model, (but not within the diagram), navigating immediately to the properties tab for that actor.

Tip

This method of creating a new actor may be confusing. It is much better to create an actor on the diagram.

Delete

This deletes the selected actor from the model.

Warning

This is a deletion from the model not just the diagram. To delete an actor from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

17.2.3. Property Fields For Actor

Name

Text box. The name of the actor. The diagram shows this name below the stick man figure. Since an actor is a classifier, it would be conventional to Capitalize the first letter (and initial letters of any component words), e.g. RemoteSensor.

Note

ArgoUML does not enforce any naming convention for actors.

Stereotype

Drop down selector. Actor is provided by default with the UML standard stereotypes (meta-class, powertype, process, thread, utility) for classifiers. Stereotypes are of limited value with actors. The stereotypes machine, organization, person and singleton are probably of most use. However, they are not provided by default with ArgoUML.

Navigate Stereotype

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace

Text box. Records the namespace for the actor. This is the package hierarchy.

Modifiers

Check box, with entries Abstract, Leaf and Root.

• Abstract is used to declare that this actor cannot be instantiated, but must always be specialized.
Caution

While actors can be specialized and generalized, it is not clear that an abstract actor has any meaning. Perhaps it might be used to indicate an actor that does not itself interact with a use case, but whose children do.

- **leaf** indicates that this actor can have no further children, while **Root** indicates it is a top level actor with no parent.

**Generalizations**

Text area. Lists any actor that generalizes this actor.

Button 1 double click navigates to the generalization and opens its property tab.

**Specializations**

Text box. Lists any specialized actor (i.e. for which this actor is a generalization. The specialized actors can communicate with the same use case instances as this actor.

Button 1 double click navigates to the generalization and opens its property tab.

**Association Ends**

Text area. Lists any association ends of associations connected to this actor.

Button 1 double click navigates to the selected entry.

17.3. Use Case

A use case represents a complete meaningful “chunk” of activity by the system in relation to its external users (actors), human or machine. It represents the primary route through which requirements are captured for the system under construction.

Within the UML metamodel, use case is a sub-class of **classifier**.

The use case icon is an oval (see Figure 17.1, “Possible artifacts on a use case diagram.”). It may be split in two, with the lower compartment showing extension points.

Caution

By default ArgoUML does not show the extension point compartment. It may be revealed by the context sensitive **Show** menu (using button 2 click), or from the Presentation tab.

17.3.1. Use Case Details Tabs

The details tabs that are active for use cases are as follows.

- **ToDoItem**
  - Standard tab.

- **Properties**
See Section 17.3.2, “Use Case Property Toolbar” and Section 17.3.3, “Property Fields For Use Case” below.

Documentation
Standard tab. See Section 13.4, “Documentation Tab”.

Presentation
Standard tab. The Fill color is used for the use case oval.

The Display: Extension Points check box is used to control whether an extension point compartment is displayed.

Source
Standard tab. It would not be usual to provide any code for a use case, since it is primarily a vehicle for capturing requirements about the system under construction, not creating the solution.

Tagged Values
Standard tab. In the UML metamodel, UseCase has the following standard tagged values defined.

• persistence (from the superclass, Classifier). Values transitory, indicating state is destroyed when an instance is destroyed or persistent, marking state is preserved when an instance is destroyed.

    Tip

    In general the instantiation of use cases is not a major aspect of any design method (they are mostly concerned with requirements capture. For most OOA&D methodologies, this tag can safely be ignored.

• semantics (from the superclass, Classifier). The value is a specification of the semantics of the use case.

• derived (from the superclass, ModelElement). Values true, meaning the use case is redundant??it can be formally derived from other elements, or false meaning it cannot.

    Note

    Derived use cases still have their value in analysis to introduce useful names or concepts.

Checklist
Standard tab for a Classifier.

17.3.2. Use Case Property Toolbar

Go up
Navigate up through the package structure of the model.

New use case
This creates a new use case within the model, (but not within the diagram), and shows immediately the properties tab for that use case.

    Tip
This method of creating a new use case can be confusing. It is much better to create a new use case on the diagram of your choice.

**New extension point**

This creates a new use extension point within the namespace of the current use case, with the current use case as its associated use case, navigating immediately to the properties tab for that extension point.

**Delete**

This deletes the selected use case from the model.

**Warning**

This is a deletion from the model *not* just the diagram. To delete a use case from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

### 17.3.3. Property Fields For Use Case

**Name**

Text box. The name of the use case. Since a use case is a classifier, it would be conventional to Capitalize the first letter (and initial letters of any component words), e.g. RemoteSensor. The name is shown inside the oval representation of the use case on the diagram.

**Note**

ArgoUML does not enforce any naming convention for use cases

**Stereotype**

Drop down selector. Use case is provided by default with the UML standard stereotypes (*metaclass, powertype, process, thread, utility*) for classifiers. Stereotyping can be useful when creating use cases in the problem domain (requirements capture) and solution domain (analysis), but none of the predefined stereotypes are well suited to this.

**Navigate Stereotype**

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Namespace**

Text box. Records the namespace for the use case. This is the package hierarchy.

**Modifiers**

Check box, with entries Abstract Leaf and Root.

- **Abstract** is used to declare that this actor cannot be instantiated, but must always be specialized.
• **Leaf** indicates that this use case can have no further children, while **Root** indicates it is a top level use case with no parent.

**Extension Points**

Text box. If this use case is, or can be extended, this field lists the extension points for the use case.

**Note**

Extension points are listed by their location point rather than their name.

Where an extension point has been created (see below), button 1 Double Click will navigate to that relationship. Button 2 gives a pop up menu with one entry.

• **New.** Add a new extension point and navigate to it, making this use case the owning use case of the extension point.

**Generalizations**

Text area. Lists use cases which are generalizations of this one. Will be set whenever a generalization is created on the from this Use Case. Button 1 Double Click on a generalization will navigate to that generalization.

**Specializations**

Text box. Lists any specialized use case (i.e. for which this use case is a generalization.

Button 1 double click navigates to the generalization and opens its property tab.

**Extends**

Text box. Lists any class that is extended by this use case.

Where an extends relationship has been created, button 1 double click will navigate to that relationship.

**Includes**

Text box. Lists any use case that this use case includes.

Where an include relationship has been created, button 1 Double Click will navigate to that relationship.

**Association Ends**

Text box. Lists any association ends (see Section 18.11, “Association”) of associations connected to this use case.

Button 1 double click navigates to the selected entry.

## 17.4. Extension Point

An extension point describes a point in a use case where an extending use case may provide additional behavior.

Examples for a travel agent sales system might be the use case for paying for a ticket, which has an extension point in the specification of the payment. Extending use cases may then extend at this point to
pay by cash, credit card etc.

Within the UML metamodel, **Extension Point** is a sub-class of **ModelElement**. A use case may display an extension point compartment (see Section 17.3, “Use Case” for details), in which extension points are shown with the following syntax.

\[
name : location.
\]

### 17.4.1. Extension Point Details Tabs

The details tabs that are active for extension points are as follows.

**ToDoItem**
- Standard tab.

**Properties**
- See Section 17.4.2, “Extension Point Property Toolbar” and Section 17.4.3, “Property Fields For Extension Point” below.

**Documentation**
- Standard tab. See Section 13.4, “Documentation Tab”.

**Source**
- Standard tab. It would not be usual to provide any code for an extension point, since it is external to the system.

**Note**
- The source tab content can be changed, but this has no effect.

**Tagged Values**
- Standard tab. In the UML metamodel, **ExtensionPoint** has the following standard tagged values defined.
  - **derived** (from the superclass, **ModelElement**). Values true, meaning the extension point is redundant—??it can be formally derived from other elements, or false meaning it cannot.

**Note**
- It is not clear how derived extension points could have any value in analysis.

### 17.4.2. Extension Point Property Toolbar

**Go up**
- Navigate up to the use case which owns this extension point.

**New Extension Point**
- This creates a new Extension Point below the selected extension point, navigating immediately to the properties tab of the newly created extension point.
New Stereotype

This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected extension point, navigating immediately to the properties tab for that stereotype.

Delete

This deletes the selected extension point from the model.

17.4.3. Property Fields For Extension Point

Name

Text box. The name of the extension point.

Tip

It is quite common to leave extension points unnamed in use case analysis, since they are always listed (within use cases and extend relationships) by their location.

Note

ArgoUML does not enforce any naming convention for extension points.

Stereotype

Drop down selector. ArgoUML does not provide any stereotypes for extension points.

Tip

Stereotyping does not have great value on an extension point.

Navigate Stereotype

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Location

Text box. A description of the location of this extension point within the owning use case.

Tip

Extension points are always listed (within use cases and extend relationships) by their location. Typically this will be the number/name of the paragraph in the specification.

Base Use Case

Text box. Shows the base use case within which this extension point is defined. Button 1 Double Click will navigate to the use case.

Extend

Text box. Lists all use cases which extend the base use case through this extension point.
Where an extending use case exists, button 1 double click will navigate to that relationship.

17.5. Association

An association on a use case diagram represents a relationship between an actor and a use case showing that actor's involvement in the use case. The invocation of the use case will involve some (significant) change perceived by the actor.

Associations are described fully under class diagrams (see Section 18.11, “Association”).

17.6. Association End

Association ends are described under class diagrams (see Section 18.12, “Association End”).

17.7. Dependency

Dependencies are described under class diagrams (see Section 18.13, “Dependency”).

Caution

Dependency has little use in use case diagrams. It is provided, because earlier versions of ArgoUML used it (incorrectly) to implement include and extends relationships.

17.8. Generalization

Generalization is a relationship between two use cases or two actors. Where A is a generalization of B, it means A describes more general behavior and B a more specific version of that behavior.

Examples for a travel agent sales system might be the use case for making a booking as a generalization of the use case for making a flight booking and a salesman actor being a generalization of a supervisor actor (since supervisors can also act as salesmen, but not vice versa).

Generalization is analogous to class inheritance within OO programming.

Note

It is easy to confuse extends relationships between use cases with generalization. However extends is about augmenting a use case's behavior at a specific point. Generalization is about specializing the behavior throughout the use case.

Within the UML metamodel, Generalization is a sub-class of Relationship.

Generalization is represented as an arrow with white filled head from the specialized use case or actor to the generalized use case or actor (see Figure 17.1, “Possible artifacts on a use case diagram.”).

17.8.1. Generalization Details Tabs

The details tabs that are active for associations are as follows.
Standard tab.

Properties
See Section 17.8.2, “Generalization Property Toolbar” and Section 17.8.3, “Property Fields For Generalization” below.

Documentation
Standard tab. See Section 13.4, “Documentation Tab”.

Presentation
Standard tab

**Note**

The values for the bounds of the generalization are downlighted, since they have no meaning, given that the generalization is tied to a particular actor and use case.

Source
Standard tab. You would not expect to generate any code for a generalization end so this is empty.

Tagged Values
Standard tab. In the UML metamodel, Generalization has the following standard tagged values defined.

- **derived** (from the superclass, ModelElement). Values true, meaning the generalization is redundant? it can be formally derived from other elements, or false meaning it cannot.

  **Note**

  Derived generalizations still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

17.8.2. Generalization Property Toolbar

**Go up**

Navigate up through the package structure of the model. For a generalization this will be the package containing the generalization.

**New Stereotype**

This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected generalization, navigating immediately to the properties tab for that generalization.

**Delete**

This deletes the selected generalization from the model.

**Warning**

This is a deletion from the model not just the diagram. To delete a generalization from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).
17.8.3. Property Fields For Generalization

Name
Text box. The name of the generalization.

Tip
It is quite common to leave generalizations unnamed in use case analysis.

Note
ArgoUML does not enforce any naming convention for associations.

Note
There is no representation of the name of a generalization on the diagram.

Stereotype
Drop down selector. Generalization is provided by default with the UML standard stereotype implementation. The stereotype is shown between ?? and ?? above or across the generalization.

Tip
Stereotyping generalization does not have great value on a use case diagram. The standard stereotype is about implementation, and suited to the use of generalization on class diagrams.

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Discriminator
Text box. The name of a discriminator for the specialization. UML 1.3 allows grouping of specializations into a number of sets, on the basis of this value.

Tip
The empty string “” is a valid entry (and the default) for this field. The discriminator is only of practical use in cases of multiple inheritance. A (class diagram) example is shown in Figure 17.2, “Example use of a discriminator with generalization”. Here each type of user should inherit from two sorts of user. One distinguishing between local or remote user (which can be identified by one discriminator) and one indicating their function as a user (identified by a different discriminator).

There is little point in using this within a use case diagram.

Namespace
Text box. Records the namespace for the generalization. This is the package hierarchy.
**Parent**

Text box. Shows the use case or actor that is the *parent* in this relationship, i.e. the more general end of the relationship. Button 1 Double Click on this entry will navigate to that use case or actor. Button 2 click will give a pop up menu, with a single entry, *Open* which will also navigate to that use case or actor.

**Child**

Text box. Shows the use case or actor that is the *child* in this relationship, i.e. the more specific end of the relationship. Button 1 Double Click on this entry will navigate to that use case or actor. Button 2 click will give a pop up menu, with a single entry, *Open* which will also navigate to that use case or actor.

**Powertype**

Drop down selector providing access to all standard UML types provided by ArgoUML and all new classes created within the current model.

This is the type of the child entity of the generalization.

**Tip**

This can be ignored for use case analysis. The only sensible value to put in would be the child use case type (as a classifier, this appears in the drop down list).

---

**Figure 17.2. Example use of a discriminator with generalization**

### 17.9. Extend

Extend is a relationship between two use cases. Where A extends B, it means A describes more specific behavior and B the general version of that behavior.

In many respects extend is like generalization. However the key difference is that the extended use case defines *extension points* (see Section 17.4, “Extension Point”), which are the only places where its behavior may be extended. The extending use case must define at which of these extension points it adds behavior.

This makes the use of extend more tightly controlled than general extension, and it is thus preferred wherever possible.

Examples for a travel agent sales system might be the use case for paying for a ticket, which has an extension point in the specification of the payment. Extending use cases may then extend at this point to pay by cash, credit card etc.

Within the UML metamodel, Extend is a sub-class of Relationship.

An extend relationship is represented as a dotted link with an open arrow head and a label `??extend??`. If a condition is defined, it is shown under the `??extend??` label (see Figure 17.1, “Possible artifacts on a use case diagram.”).

### 17.9.1. Extend Details Tabs
The details tabs that are active for extend relationships are as follows.

**Note**

There is no source tab, since there is no source code that could be generated for an extend relationship.

**ToDoItem**

Standard tab.

**Properties**

See Section 17.9.2, “Extend Property Toolbar” and Section 17.9.3, “Property Fields For Extend” below.

**Documentation**

Standard tab. See Section 13.4, “Documentation Tab”.

**Presentation**

Standard tab

**Note**

The values for the bounds are downlighted, since the extend is tied to a particular pair of use cases.

**Source**

Standard tab. You would not expect to generate any code for an extend relationship so this is empty.

**Tagged Values**

Standard tab. In the UML metamodel, Extend has the following standard tagged values defined.

- derived (from the superclass, ModelElement). Values true, meaning the extend relationship is redundant or false meaning it cannot.

**Note**

Derived extend relationships could have their value in analysis to introduce useful names or concepts.

### 17.9.2. Extend Property Toolbar

**Go up**

Navigate up through the package structure of the model. For a extend this will be the package containing the extend.

**New extension point**

This creates a new use case extension point within the namespace of the current extend relationship, with the current extend relationship as its first extending relationship.

**Tip**
While it is perfectly valid to create extension points from an extend relationship, the created extension point will have no associated use case (it can subsequently be set up).

It would be more usual to instead create the extension point within a use case and subsequently link to it from an extend relationship (see Section 17.9.3, “Property Fields For Extend” below).

**New Stereotype**

This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected extent relationship, navigating immediately to the properties tab for that stereotype.

**Delete**

This deletes the selected extend relationship from the model.

**Warning**

This is a deletion from the model *not* just the diagram. To delete a extend from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

### 17.9.3. Property Fields For Extend

**Name**

Text box. The name of the extend relationship.

**Tip**

It is quite common to leave extends unnamed in use case analysis.

**Note**

ArgoUML does not enforce any naming convention for extend relationships.

**Stereotype**

Drop down selector. ArgoUML does not provide any stereotypes by default.

**Tip**

Stereotyping does not have great value on an extend relationship.

**Note**

There is no representation of the stereotype of an extend relationship on the diagram.
Navigate Stereotype icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace

Text box. Records the namespace for the extend relationship. This is the package hierarchy.

Button 1 Double Click on the entry will navigate to the package defining this namespace (or the model for the top level namespace).

Base Use Case

Drop down selector. Shows the use case that is being extended by this extend relationship. Button 1 click on this entry will give a drop down menu of all available use cases (and an empty entry) which may be selected by button 1 click.

Extension

Drop down selector. Show the use case that is doing the extending through this extend relationship. Button 1 click on this entry will give a drop down menu of all available use cases (and an empty entry) which may be selected by button 1 click.

Extension Points

Text box. If this use case is, or can be extended, this field lists the extension points for the use case.

Note

Extension points are listed by their location point rather than their name.

Where an extension point has been created, button 1 double click will navigate to that relationship. Button 2 gives a pop up menu with two entries.

- Add. The “Ad/Remove ExtensionPoints” window opens. In this window it is possible to build a list of extension points.

- New. Add a new extension point in the list and navigate to it. The current extend relationship is added as the first in list of extending relationships of the new extension point.

Condition

Text area. Multi-line textual description of any condition attached to the extend relationship.

17.10. Include

Include is a relationship between two use cases. Where A includes B, it means B described behavior that is to be included in the description of the behavior of A at some point (defined internally by A).

Examples for a travel agent sales system might be the use case for booking travel, which includes use cases for booking flights and taking payment.

Within the UML metamodel, Include is a sub-class of Relationship.

An include relationship is represented as a dotted link with an open arrow head and a label ??include?? (see Figure 17.1, “Possible artifacts on a use case diagram.”).
17.10.1. Include Details Tabs

The details tabs that are active for include relationships are as follows.

Note

There is no source tab, since there is no source code that could be generated for an include relationship.

ToDoItem
Standard tab.

Properties
See Section 17.10.2, “Include Property Toolbar” and Section 17.10.3, “Property Fields For Include” below.

Documentation
Standard tab. See Section 13.4, “Documentation Tab”.

Presentation
Standard tab

Note

The values for the bounds of the include relationships are downlighted, since the include relationship is represented by a line between a particular pair of use cases.

Tagged Values
Standard tab. In the UML metamodel, Include has the following standard tagged values defined.

• derived (from the superclass, ModelElement). Values true, meaning the include relationship is redundant it can be formally derived from other elements, or false meaning it cannot.

Note

Derived include relationships could have their value in analysis to introduce useful names or concepts.

17.10.2. Include Property Toolbar

Go up
Navigate up through the package structure of the model. For a include this will be the package containing the include.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected include relationship, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the selected include relationship from the model.
Warning

This is a deletion from the model not just the diagram. To delete a include from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

17.10.3. Property Fields For Include

Name

Text box. The name of the include relationship.

Tip

It is quite common to leave include relationships unnamed in use case analysis.

Note

ArgoUML does not enforce any naming convention for include relationships.

Stereotype

Drop down selector. ArgoUML does not provide any stereotypes for include relationships.

Tip

Stereotyping does not have great value on an include relationship.

Note

There is no representation of the stereotype of an include relationship on the diagram.

Navigate Stereotype

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace

Text box. Records the namespace for the include. This is the package hierarchy.

Button 1 click on the entry will navigate to the package defining this namespace (or the model for the top level namespace).

Base Use Case

Drop down selector. Records the use case that is doing the including in this include relationship. Button 1 click on this entry will give a drop down menu of all available use cases which may be selected by button 1 click.

Included Use Case
Drop down selector. Records the use case that is being included by this include relationship. Button 1 click on this entry will give a drop down menu of all available use cases (and an empty entry) which may be selected by button 1 click.
Chapter 18. Class Diagram Artifact Reference

18.1. Introduction

This chapter describes each artifact that can be created within a class diagram. Note that some sub-artifacts of artifacts on the diagram may not actually themselves appear on the diagram.

Class diagrams are used for only one of the UML static structure diagrams, the class diagram itself. Object diagrams are represented on the ArgoUML deployment diagram.

In addition, ArgoUML uses the class diagram to show model structure through the use of packages.

There is a close relationship between this material and the Properties Tab of the Details Pane (see Section 13.3, “Properties Tab”). That section covers Properties in general, in this chapter they are linked to specific artifacts.

Figure 18.1, “Possible artifacts on a class diagram.” shows a class diagram with all possible artifacts displayed.

Figure 18.1. Possible artifacts on a class diagram.

Figure 18.2, “Possible artifacts on a package diagram.” shows a package diagram with all possible artifacts displayed.

Figure 18.2. Possible artifacts on a package diagram.

18.1.1. Limitations Concerning Class Diagrams in ArgoUML

The current implementation does not allow datatypes to be shown on class diagrams.

A variant of the class diagram within the UML standard is the object diagram. There is currently no support for objects or links within ArgoUML Class diagrams. Instead the ArgoUML deployment diagram does have both objects and links, and can be used to draw object diagrams.

18.2. Package

The package is the main organizational artifact within ArgoUML. In the UML metamodel it is a subclass of both Namespace and GeneralizableElement.

Note

ArgoUML also implements the UML Model artifact as a sub-class of package, but not the Subsystem artifact.
ArgoUML also implements some less common aspects of UML model management. In particular the relationship UML 1.4 defines as Generalization and the sub-class dependency Permission for use between packages.

18.2.1. Package Details Tabs

The details tabs that are active for packages are as follows.

**ToDoItem**
- Standard tab.

**Properties**
- See Section 18.2.2, “Package Property Toolbar” and Section 18.2.3, “Property Fields For Package” below.

**Documentation**
- Standard tab. See Section 13.4, “Documentation Tab”.

**Presentation**
- Standard tab. The **Bounds**: field defines the bounding box for the package on the diagram.

**Source**
- Standard tab. This contains a template package declaration appropriate to the entire package. In the future this would be part of the code generation activity.

**Tagged Values**
- Standard tab. In the UML metamodel, Package has the following standard tagged values defined.
  - derived (from the superclass, ModelElement). Values true, meaning the package is redundant??it can be formally derived from other elements, or false meaning it cannot.

**Note**
- Derived packages still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

18.2.2. Package Property Toolbar

**Go up**
- Navigate up through the package structure.

**New Package**
- This creates a new package within the package (which appears on no diagram), navigating immediately to the properties tab for that package.

**New Datatype**
- This creates a new Datatype (see Section 16.3, “Datatype”) for the selected package, navigating immediately to the properties tab for that datatype.

**New Stereotype**
- This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected package, navigating
immediately to the properties tab for that stereotype.

**Delete Package**
Deletes the package from the model.

**Warning**
This is a deletion from the model *not* just the diagram. To delete a package from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

### 18.2.3. Property Fields For Package

**Name**
Text box. The name of the package. The name of a package, like all packages, is by convention all lower case, not containing any periods.

**Note**
By default a new package has no name defined. The package will appear with the name *(anon Package)* in the explorer.

**Stereotype**
Drop down selector. Package is provided by default with the UML standard stereotypes for package *(facade, framework, metamodel, stub, topLevel, systemModel)*.

**Navigate Stereotype**
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 18.4, “Stereotype”).

**Namespace**
Drop down selector. Records the namespace for the package. This is the package hierarchy.

**Visibility**
Radio box, with four entries public, private, protected, and package. Indicates whether the package is visible outside the package.

**Modifiers**
Check box, with entries abstract, leaf and root.

- **Abstract** is used to declare that this package cannot be instantiated, but must always be specialized.

**Tip**
The meaning of abstract applied to a package if not that clear. It might mean that the package contains interfaces or abstract classes without realizations. This is probably better handled through stereotyping of the package (for example ??facade??).
• **Leaf** indicates that this package can have no further subpackages.

• **Root** indicates that it is the top level package.

**Tip**

Within ArgoUML **Root** only meaningfully applies to the Model, since all packages sit within the model. This could be used to emphasize that the Model is at the top level.

**Generalizations**

Text area. Lists any package that generalizes this package.

Button 1 double click navigates to the generalization and opens its property tab.

**Specializations**

Text box. Lists any specialized package (i.e. for which this package is a generalization).

button 1 double click navigates to the generalization and opens its property tab.

**Owned Elements**

Text area. A listing of all the packages, classes, interfaces, datatypes, actors, use cases, associations, generalizations and stereotypes within the package.

Button 1 double click on any item listed here navigates to that artifact.

### 18.3. Datatype

Datatypes are not specific to packages or class diagrams, and are discussed within the chapter on top level artifacts (see Section 16.3, “Datatype”).

### 18.4. Stereotype

Stereotypes are not specific to packages or class diagrams, and are discussed within the chapter on top level artifacts (see Section 16.5, “Stereotype”).

### 18.5. Class

The class is the dominant artifact on a class diagram. In the UML metamodel it is a sub-class of Classifier and GeneralizableElement.

A class is represented on a class diagram as a rectangle with three horizontal compartments. The top compartment displays the class name (and stereotype), the second compartment any attributes and the third any operations. The last two compartments may optionally be hidden.

### 18.5.1. Class Details Tabs

The details tabs that are active for classes are as follows.
ToDoItem
Standard tab.

Properties
See Section 18.5.2, “Class Property Toolbar” and Section 18.5.3, “Property Fields For Class” below.

Documentation
Standard tab. See Section 13.4, “Documentation Tab”.

Presentation
Standard tab. The tick boxes, Attributes and Operations allow the attributes and operations compartments to be shown (the default) or hidden. This is a setting valid for only the current diagram that shows the class. The Bounds: field defines the bounding box for the package on the diagram.

Source
Standard tab. This contains a template for the class declaration and declarations of associated classes.

Constraints
Standard tab. There are no standard constraints defined for Class within the UML metamodel.

Tagged Values
Standard tab. In the UML metamodel, Class has the following standard tagged values defined.

- persistence (from the superclass, Classifier). Values transitory, indicating state is destroyed when an instance is destroyed or persistent, marking state is preserved when an instance is destroyed.

- semantics (from the superclass, Classifier). The value is a specification of the semantics of the class.

- derived (from the superclass, ModelElement). Values true, meaning the class is redundant? It can be formally derived from other elements, or false meaning it cannot.

Note
Derived classes still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

Note
The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

Checklist
Standard tab for a Classifier.

18.5.2. Class Property Toolbar
Go up
  Navigate up through the package structure.

New attribute
  This creates a new attribute (see Section 18.6, “Attribute”) within the class, navigating immediately to the properties tab for that attribute.

New operation
  This creates a new operation (see Section 18.7, “Operation”) within the class, navigating immediately to the properties tab for that operation.

New reception
  This creates a new reception, navigating immediately to the properties tab for that reception.

New inner class
  This creates a new inner class (which appears on no diagram) within the class. This belongs to the class and is restricted to the namespace of the class. It exactly models the Java concept of inner class. As an inner class it needs no attributes or operations, since it shares those of its owner.

  **Note**
  Inner class is not a separate concept in UML. This is a convenient shorthand for creating a class that is restricted to the namespace of its owning class.

New class
  This creates a new class (which appears on no diagram) within the same namespace as the current class.

New Stereotype
  This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected class, navigating immediately to the properties tab for that stereotype.

Delete
  This deletes the class from the model

  **Warning**
  This is a deletion from the model not just the diagram. To delete a class from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

18.5.3. Property Fields For Class

Name
  Text box. The name of the class. The name of a class has a leading capital letter, with words separated by “bumpy caps”.

  **Note**
  The ArgoUML critics will complain about class names that do not have an initial capital.
Stereotype

Drop down selector. Class is provided by default with the UML standard stereotypes for Class (implementationClass and type) and for Classifier (metaclass, powertype, process, thread and utility).

Tip

One stereotype that is not part of the UML standard, but is widely used is Singleton, used to distinguish classes which have a single static instance, and no public constructor. Although not part of ArgoUML by default, this stereotype is understood by the critics. You may find it useful to create this stereotype for yourself (see Section 16.5, “Stereotype”).

Navigate Stereotype

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 18.4, “Stereotype”).

Namespace

Drop down selector. Records and allows setting of the namespace for the class. This is the package hierarchy.

Button 1 click on the entry will move the class to the selected namespace.

Modifiers

Check box, with entries Abstract, Leaf, Root, and Active.

• Abstract is used to declare that this class cannot be instantiated, but must always be subclassed. The name of an abstract class is displayed in italics on the diagram.

Caution

If a class has any abstract operations, then it should be declared abstract. ArgoUML will not enforce this.

• Leaf indicates that this class cannot be further subclassed, while Root indicates it can have no superclass. It is possible for a class to be both Abstract and Leaf, since its static operations may still be referenced.

• Active indicates that this class exhibits dynamic behavior (and is thus associated with a state or activity diagram).

Visibility

Radio box, with four entries public, private, protected, and package. Indicates whether the class is visible outside the namespace.

Client Dependencies

Text area. Lists the “depending” ends of the relationship, i.e. the end that makes use of the other end.

Button 1 double click navigates to the dependency and opens its property tab.

Supplier Dependencies

Text area. Lists the “supplying” ends of the relationship, i.e. the end supplying what is needed by the other end.
Button 1 double click navigates to the dependency and opens its property tab.

Generalizations
Text area. Lists any class that generalizes this class.

Button 1 double click navigates to the generalization and opens its property tab.

Specializations
Text box. Lists any specialized class (i.e. for which this class is a generalization).

Button 1 double click navigates to the generalization and opens its property tab.

Attributes
Text area. Lists all the attributes (see Section 18.6, “Attribute”) defined for this class. Button 1 double click navigates to the selected attribute. Button 2 gives a pop up menu with two entries, which allow reordering the attributes.

- **Move Up.** Only available where there are two or more attributes listed, and the attribute selected is not at the top. It moves the attribute up one position.
- **Move Down.** Only available where there are two or more attributes listed, and the attribute selected is not at the bottom. It moves the attribute down one position.

Association Ends
Text box. Lists any association ends (see Section 18.11, “Association”) of associations connected to this class.

Button 1 double click navigates to the selected entry.

Operations
Text area. Lists all the operations (see Section 18.7, “Operation”) defined on this class. Button 1 click navigates to the selected operation. Button 2 gives a pop up menu with two entries, which allow reordering the operations.

- **Move Up.** Only available where there are two or more operations listed, and the operation selected is not at the top. It moves the operation up one position.
- **Move Down.** Only available where there are two or more operations listed, and the operation selected is not at the bottom. It moves the operation down one position.

Owned Elements
Text area. A listing of artifacts contained within the classes' namespace. This is where any inner class (see Section 18.5.2, “Class Property Toolbar”) will appear

Button 1 double click on any of the artifacts navigates to that artifact.

**Tip**

Most namespace hierarchies should be managed through the package mechanism. Namespace hierarchies through classes are best restricted to inner classes. Conceivable datatypes, signals and interfaces could also appear here, but actors and use cases would seem of no value.

### 18.6. Attribute

Attribute is a named slot within a class (or other Classifier) describing a range of values that may
be held by instances of the class. In the UML metamodel it is a sub-class of StructuralFeature which is itself a sub-class of Feature.

An attribute is represented in the diagram on a single line within the attribute compartment of the class. Its syntax is as follows:

\[ \text{visibility} \ \text{attributeName} : \text{type} \ [= \text{initialValue}] \]

\text{visibility} is +, #, – or ~ corresponding to public, protected, private, or package visibility respectively.

\text{attributeName} is the actual name of the attribute being declared.

\text{type} is the type (UML datatype, class or interface) declared for the attribute.

\text{initialValue} is any initial value to be given to the attribute when an instance of the class is created. This may be overridden by any constructor operation.

In addition any attribute declared static will have its whole entry underlined on the diagram.

### 18.6.1. Attribute Details Tabs

The details tabs that are active for attributes are as follows.

- **ToDoItem**
  - Standard tab.

- **Properties**
  - See Section 18.6.2, “Attribute Property Toolbar” and Section 18.6.3, “Property Fields For Attribute” below.

- **Documentation**
  - Standard tab. See Section 13.4, “Documentation Tab”.

- **Source**
  - Standard tab. This contains a declaration for the attribute.

- **Constraints**
  - Standard tab. There are no standard constraints defined for Attribute within the UML metamodel.

- **Tagged Values**
  - Standard tab. In the UML metamodel, Attribute has the following standard tagged values defined.
    - **transient**.
    - **volatile**. This is an ArgoUML extension to the UML 1.4 standard to indicate that this attribute is realized in some volatile form (for example it will be a memory mapped control register).

**Note**

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.
Checklist
Standard tab for a Attribute.

18.6.2. Attribute Property Toolbar

Go up
Navigate up through the package structure.

New attribute
This creates a new attribute within the owning class of the current attribute, navigating immediately to the properties tab for that attribute.

Tip
This is a very convenient way to add a number of attributes, one after the other, to a class.

New Datatype
This creates a new Datatype (see Section 16.3, “Datatype”) for the selected attribute, navigating immediately to the properties tab for that datatype.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected attribute, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the attribute from the model

Warning
This is a deletion from the model not just the diagram. If desired the whole attribute compartment can be hidden on the diagram using the style tab (see Section 18.6.2, “Attribute Property Toolbar”) or the button 2 pop up menu for the class on the diagram.

18.6.3. Property Fields For Attribute

Name
Text box. The name of the attribute. The name of a attribute has a leading lower case letter, with words separated by “bumpy caps”.

Note
The ArgoUML critics will complain about attribute names that do not have an initial lower case letter.

Stereotype
Drop down selector. There are no UML standard stereotypes for Attribute.

**Navigate Stereotype**

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Owner**

Text box. Records the class which contains this attribute.

Button 1 double click on the entry will navigate to the class.

**Multiplicity**

Editable drop down selector. The default value (1) is that there is one instance of this attribute for each instance of the class, i.e. it is a scalar. The drop down provides a number of commonly used specifications for non-scalar attributes.

**Note**

ArgoUML presents a number of predefined ranges for multiplicity for easy access. The user may also enter any user defined range that follows the UML syntax, such as “1..3,7,10”.

The value 1..1 is equivalent to the default (exactly one scalar instance). The selection 0..1 indicates an optional scalar attribute.

**Type**

Drop down selector. The type of this attribute. This can be any UML Classifier, although in practice only Class, DataType, or Interface make any sense.

**Note**

A type must be declared (it can be void). By default ArgoUML supplies int as the type.

**Navigate Type**

icon. This will navigate to the property panel for the currently selected type. (see Section 18.5, “Class”, Section 18.3, “Datatype” and Section 18.15, “Interface”).

**Initial Value**

Text box with drop down. This allows you to set an initial value for the attribute if desired (this is optional). The drop down menu provides access to the common values 0, 1, 2, and null.

**Caution**

Any constructor operation may ignore this initial value.

**Visibility**

Radio box, with entries public, private, protected and package.

- **public**. The attribute is available to any artifact that can see the owning class.
- **private**. The attribute is available only to the owning class (and any inner classes).
• **protected.** The attribute is available only to the owning class, or artifacts that are subclasses of the owning class.

• **package.** The attribute is available only to artifacts contained in the same package.

**Changeability**

Radio box, with entries `addOnly`, `changeable`, and `frozen`.

• **addOnly.** Meaningful only if the multiplicity is not fixed to a single value. Additional values may be added to the set of values, but once created a value may not be removed or altered.

• **changeable.** There are no restrictions of modification.

• **frozen.** Also named “immutable”. The value of the attribute may not change during the lifetime of the owner class. The value must be set at object creation, and may never change after that. This implies that there is usually an argument for this value in a constructor and that there is no operation that updates this value.

**Static**

Check box for `static`. If unchecked (the defaults) then the attribute has “instance scope”. If checked, then the attribute is static, i.e. it has “class scope”. Static attributes are indicated on the diagram by underlining.

### 18.7. Operation

An operation is a service that can be requested from an object to effect behavior. In the UML metamodel it is a sub-class of `BehavioralFeature` which is itself a sub-class of `Feature`.

In the diagram, an operation is represented on a single line within the operation compartment of the class. Its syntax is as follows:

```
visibility name (parameter list) : return-type-expression [property-string]
```

You can edit this line directly in the diagram, by double-clicking on it. All elements are optional and, if left unspecified, the old values will be preserved.

A **stereotype** can be given between any two elements in the line in the format: `<<stereotype>>`.

The following properties are recognized to have special meaning: `abstract`, `concurrency`, `concurrent`, `guarded`, `leaf`, `query`, `root` and `sequential`.

The **visibility** is `+`, `#`, `–` or `~` corresponding to `public`, `protected`, `private` visibility, or `package` visibility respectively.

`static` and `final` optionally appear if the operation has those modifiers. Any operation declared static will have its whole entry underlined on the diagram.

There may be zero or more entries in the **parameter list** separated by commas. Every entry is a pair of the form:

```
name : type
```

The **return-type-expression** is the type (UML datatype, class or interface) of the result returned.
Finally the whole entry is shown in italics if the operation is declared abstract.

18.7.1. Operation Details Tabs

The details tabs that are active for operations are as follows.

ToDoItem
   Standard tab.

Properties
   See Section 18.7.2, “Operation Property Toolbar” and Section 18.7.3, “Property Fields For Operation” below.

Documentation
   Standard tab. See Section 13.4, “Documentation Tab”.

Presentation
   Standard tab. The Bounds: field does allow editing, but the changes have no effect.

Source
   Standard tab. This contains a declaration for the operation.

Constraints
   Standard tab. There are no standard constraints defined for Operation within the UML metamodel.

Tagged Values
   Standard tab. In the UML metamodel, Operation has the following standard tagged values defined.

   • semantics. The value is a specification of the semantics of the operation.

   • derived (from the superclass, ModelElement). Values true, meaning the operation is redundant??it can be formally derived from other elements, or false meaning it cannot.

   Note
   Derived operations still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

   Note
   The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML

Checklist
   Standard tab for an Operation.

18.7.2. Operation Property Toolbar
Go up
   Navigate up through the package structure.

New operation
   This creates a new operation within the owning class of the current operation, navigating immediately to the properties tab for that operation.

   **Tip**
   This is a very convenient way to add a number of operations, one after the other, to a class.

New parameter
   This creates a new parameter for the operation, navigating immediately to the properties tab for that parameter.

New raised signal
   This creates a new raised signal for the operation, navigating immediately to the properties tab for that raised signal.

New Datatype
   This creates a new Datatype (see Section 16.3, “Datatype”) in the namespace of the owner of the operation, navigating immediately to the properties tab for that datatype.

New Stereotype
   This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected operation, navigating immediately to the properties tab for that stereotype.

Delete
   This deletes the operation from the model

   **Warning**
   This is a deletion from the model *not* just the diagram. If desired the whole operation compartment can be hidden on the diagram using the *presentation* tab (see Section 18.7.2, “Operation Property Toolbar”) or the button 2 pop up menu for the class on the diagram.

### 18.7.3. Property Fields For Operation

**Name**

   Text box. The name of the operation. The name of an operation has a leading lower case letter, with words separated by “bumpy caps”.

   **Note**
   The ArgoUML critics will complain about operation names that do not have an initial lower case letter.
Tip

If you wish to follow the Java convention of constructors having the same name as the class, you will violate this rule. Silence the critic by setting the stereotype `create` for the constructor operation.

Stereotype

Drop down selector. There are two UML standard stereotypes for `Operation` (from the parent metaclass, `BehavioralFeature`), `create` and `destroy`.

Tip

You should use `create` as the stereotype for constructors, and `destroy` for destructors (which are called “finalize” methods under Java).

Navigate Stereotype icon. If a stereotype has been selected, clicking button 1 will navigate to the stereotype property panel (see Section 18.4, “Stereotype”).

Owner Text box. Records the class which contains this operation.

Button 1 double click on the entry will navigate to the class.

Visibility

Radio box, with entries `public`, `private`, `protected` and `package`.

- `public`. The operation is available to any artifact that can see the owning class.
- `private`. The operation is available only to the owning class (and any inner classes).
- `protected`. The operation is available only to the owning class, or artifacts that are subclasses of the owning class.
- `package`. The operation is available only artifacts contained in the same package.

Modifiers

Check box, with entries `abstract`, `leaf`, `root`, `query`, and `static`.

- `abstract`. This operation has no implementation with this class. The implementation must be provided by a subclass.

Important

Any class with an abstract operation must itself be declared abstract.

- `leaf`. The implementation of this operation must not be overridden by any subclass.
- `root`. The declaration of this operation must not override a declaration of the operation from a superclass.
- `query`. This indicates that the operation must have no side effects (i.e. it must not change the state of the system). It can only return a value.
Caution

Operations for user defined datatypes must always check this modifier.

- **static.** There is only one instance of this operation associated with the class (as opposed to one for each instance of the class). This is the OwnerScope attribute of a Feature metaclass within UML. Any operation declared static is shown underlined on the class diagram.

Concurrency

Radio box, with entries **guarded, sequential, and concurrent.**

- **guarded.** Multiple calls from concurrent threads may occur simultaneously to one instance (on any guarded operation), but only one is allowed to commence. The others are blocked until the performance of the first operation is complete.

Caution

It is up to the system designer to ensure that deadlock cannot occur. It is the responsibility of the operation to implement the blocking behavior (as opposed to the system).

- **sequential.** Only one call to an instance (of the class with the operation) may be outstanding at any one time. There is no protection, and no guarantee of behavior if the system violates this rule.

- **concurrent.** Multiple calls to one instance may execute at the same time. The operation is responsible for ensuring correct behavior. This must be managed even if there are other sequential or synchronized (guarded) operations executing at the time.

Parameter

Text area, with entries for all the parameters of the operation (see Section 18.8, “Parameter”). A new operation is always created with one new parameter, return to define the return type of the operation.

Button 1 double click on any of the parameters navigates to that parameter. Button 2 click brings up a pop up menu with two entries.

- **Move Up.** Only available where there are two or more parameters, and the parameter selected is not at the top. It is moved up one position.

- **Move Down.** Only available where there are two or more parameters listed, and the parameter selected is not at the bottom. It is moved down one position.

Raised Signals

Text area, with entries for all the signals (see Section 18.9, “Signal”) that can be raised by the operation.

Caution

ArgoUML at present (V0.18) has limited support for signals. In particular they are not linked to signal events that could drive state machines.
18.8. Parameter

A parameter is a variable that can be passed. In the UML metamodel it is a sub-class of ModelElement.

A parameter is represented within the operation declaration in the operation compartment of a class as follows.

\[ \text{name : type} \]

\text{name} is the name of the parameter.

\text{type} is the type (UML datatype, class or interface) of the parameter.

The exception is any parameter representing a return value, whose type only is shown at the end of the operation declaration.

18.8.1. Parameter Details Tabs

The details tabs that are active for parameters are as follows.

ToDoItem

Standard tab.

Properties

See Section 18.8.2, “Parameter Property Toolbar” and Section 18.8.3, “Property Fields For Parameter” below.

Documentation

Standard tab. See Section 13.4, “Documentation Tab”.

Source

Standard tab. This contains a declaration for the parameter.

Tagged Values

Standard tab. In the UML metamodel, Parameter has the following standard tagged values defined.

• derived (from the superclass, ModelElement). Values true, meaning the parameter is redundant??it can be formally derived from other elements, or false meaning it cannot.

Caution

A derived parameter is a meaningless concept.

Note

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.
18.8.2. Parameter Property Toolbar

Go up
Navigate up through the package structure.

New parameter
This creates a new parameter for the for the same operation as the current parameter, navigating immediately to the properties tab for that parameter.

Tip
This is a convenient way to add a series of parameters for the same operation.

New Datatype
This creates a new Datatype (see Section 16.3, “Datatype”) in the namespace of the owner of the operation of the parameter, navigating immediately to the properties tab for that datatype.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected parameter, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the parameter from the model

Warning
This is a deletion from the model not just the diagram. If desired the whole operation compartment can be hidden on the diagram using the presentation tab or the button 2 pop up menu for the class on the diagram.

18.8.3. Property Fields For Parameter

Name
Text box. The name of the parameter. By convention, the name of a parameter has a leading lower case letter, with words separated by “bumpy caps”.

Note
The ArgoUML critics do not complain about parameter names that do not have an initial lower case letter.

Stereotype
Drop down selector. There are no UML standard stereotypes for Parameter.

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).
**Owner**

Text box. Records the operation which contains this parameter.

Button 1 double click on the entry will navigate to the operation.

**Type**

Drop down selector. The type of this parameter. This can be any UML Classifier, although in practice only Class, DataType, or Interface make any sense.

**Note**

A type must be declared (it can be void, but this only makes sense for a return parameter). By default ArgoUML supplies int as the type the first time a parameter is created, and thereafter the type of the most recently created parameter.

**Default Value**

Text box with drop down. This allows you to set an initial value for the parameter if desired (this is optional). The drop down menu provides access to the common values 0, 1, 2, and null.

**Caution**

This only makes sense for out or return parameters.

**Kind**

Radio box, with entries out, in/out, return, and in.

- **out.** The parameter is used only to pass values back from the operation.

- **in/out.** The parameter is used both to pass values in and to pass results back out of the operation.

**Note**

This is the default for any new parameter.

- **return.** The parameter is a return result from the call.

**Note**

There is nothing to stop you declaring more than one return parameter (some programming languages support this concept).

**Tip**

The name of the return parameter does not appear on the diagram, but it is convenient to give it an appropriate name (such as the default return to identify it in the list of parameters on the operation property tab.

- **in.** The parameter is used only to pass values in to the operation.
18.9. Signal

A signal is a specification of an asynchronous stimulus communicated between instances. In the UML metamodel it is a sub-class of Classifier.

Within ArgoUML signals are not fully handled. Their value is when they are received as signal events driving the asynchronous behavior of state machines and when associated with send actions in state machines and messages for collaboration diagrams.

Tip

In general there is limited value at present in defining signals within ArgoUML. It may prove more useful to define signals as classes, with a (user defined) stereotype of signal as suggested in the UML 1.4 standard. This allows any dependency relationships between signals to be shown.

18.9.1. Signal Details Tabs

The details tabs that are active for signals are as follows.

ToDoItem
   Standard tab.

Properties

Documentation
   Standard tab. See Section 13.4, “Documentation Tab”.

Source
   Standard tab. There is nothing generated for a signal.

Tagged Values

   Standard tab. In the UML metamodel, Signal has the following standard tagged values defined.

   • persistence (from the superclass, Classifier). Values transitory, indicating state is destroyed when an instance is destroyed or persistent, marking state is preserved when an instance is destroyed.

   • semantics (from the superclass, Classifier). The value is a specification of the semantics of the signal.

   • derived (from the superclass, ModelElement). Values true, meaning the signal is redundant??it can be formally derived from other elements, or false meaning it cannot.

Note

   Derived signals still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

Note
The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

18.9.2. Signal Property Toolbar

Go up
Navigate up through the package structure.

New signal
This creates a new signal, navigating immediately to the properties tab for that signal.

Caution
The signal is not associated with the same operation as the original signal, so this will have to be done afterwards.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected signal, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the signal from the model

Warning
This is a deletion from the model.

18.9.3. Property Fields For Signal

Name
Text box. The name of the signal. From their similarity to classes, by convention, the name of a signal has a leading upper case letter, with words separated by “bumpy caps”.

Note
The ArgoUML critics do not complain about signal names that do not have an initial upper case letter.

Stereotype
Drop down selector. Signal is provided by default with the UML standard stereotypes for its parent in the UML meta-model, Classifier (metaclass, powerType, process, thread, and utility).

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace
Drop down selector. Records and allows changing the namespace for the signal. This is the package hierarchy of the signal.

Contexts
Text area. Lists all the contexts defined for this signal. Button 1 double click navigates to the selected context, button 2 click brings up a pop up menu with one entry.

• Add. Add a new context. This opens the Add/Remove Contexts dialog box (see figure below), which allows choosing between all possible operations, and adding them to the selected list.

Figure 18.3. The “add/remove context” dialog box

18.10. Reception (to be written)
A reception is ...

18.11. Association
An association on a class diagram represents a relationship between classes, or between a class and an interface. On a usecase diagram, an association binds an actor to a usecase.

Within the UML metamodel, Association is a sub-class of both Relationship and GeneralizableElement.

The association is represented as a solid line connecting actor and usecase or class or interface (see Figure 18.1, “Possible artifacts on a class diagram.”). The name of the association and any stereotype appear above the line.

ArgoUML is not restricted to binary associations. See Section 18.11.1, “Three-way and Greater Associations and Association Classes” for more on this.

Associations are permitted between interfaces and classes, but UML 1.3 specifies they must only be navigable toward the interface??in other words the interface cannot see the class. ArgoUML will draw such associations with the appropriate navigation.

Associations are often not named, when their meaning is obvious from the context.

Note
ArgoUML provides no specific way of showing the direction of the association as described in the UML 1.4 standard. The naming should attempt to make this clear.

The association contains at least two ends, which may be navigated to via the association property sheet. See Section 18.12, “Association End” for more information.

18.11.1. Three-way and Greater Associations and Asso-
ciation Classes

UML 1.3 provides for N-ary associations and associations that are governed by a third associative class. Both are supported by ArgoUML.

N-ary associations are created by drawing with the association tool from an existing association to a third class. The current implementation of ArgoUML does not allow the inverse: drawing from a 3rd class towards an existing association is not possible.

Association Classes are drawn exactly like a normal association, i.e. between two classes, but with a different dedicated tool from the diagram toolbar.

18.11.2. Association Details Tabs

The details tabs that are active for associations are as follows.

ToDoItem
  Standard tab.

Properties
  See Section 18.11.3, “Association Property Toolbar” and Section 18.11.4, “Property Fields For Association” below.

Documentation
  Standard tab. See Section 13.4, “Documentation Tab”.

Presentation
  Standard tab.

Note

The values for the bounds of the Association have no meaning, since they are determined by the location of the connected items. Changing them has no effect on the diagram.

Source
  Standard tab. You would not expect to generate any code for an association, and any code entered here is ignored (it will have disappeared when you come back to the association.

Tagged Values

Standard tab. In the UML metamodel, Association has the following standard tagged values defined.

- persistence. Values transitory, indicating state is destroyed when an instance is destroyed or persistent, marking state is preserved when an instance is destroyed.

- derived (from the superclass, ModelElement). Values true, meaning the association is redundant??it can be formally derived from other elements, or false meaning it cannot.

Note

Derived associations still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.
Note

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

18.11.3. Association Property Toolbar

Go up
Navigate up through the package structure of the model. For an association this will be the package containing the association.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected association, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the selected association from the model.

Warning
This is a deletion from the model not just the diagram. To delete an association from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

18.11.4. Property Fields For Association

Name
Text box. The name of the association. By convention association names start with a lower case letter, with “bumpy caps” used to indicate words within the name, thus: salesHandling.

Note
ArgoUML does not enforce any naming convention for associations.

Tip
Although the design critics will advise otherwise, it is perfectly normal not to name associations on a class diagram, since the relationship is often obvious from the classes (or class and interface) name.

Stereotype
Drop down selector. Association is provided by default with the UML standard stereotype for Association (implicit).

Stereotyping can be useful when creating associations in the problem domain (requirements cap-
ture) and solution domain (analysis), as well as for processes based on patterns.

The stereotype is shown between ?? and ?? below the name of the association on the diagram.

**Navigate Stereotype**
- Icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Namespace**
- Drop down selector. Records and allows changing the namespace for the association. This is the package hierarchy.

**Connections**
- Text area. Lists the ends of this association. An association can have two or more ends. For more on association ends see Section 18.12, “Association End”.

The names of the association ends are listed, unless the association end has no name (the case when it is first created), in which case (anon AssociationEnd) is shown.

**Note**

The only representation of association ends on a diagram is that their name appears at the relevant end of the corresponding association.

Button 1 double click on an association end will navigate to that end.

**Association Roles**
- Text area. (To be written)

**Links**
- Text area. (To be written)

### 18.12. Association End

Two or more association ends are associated with each association (see Section 17.5, “Association”).

Within the UML metamodel, AssociationEnd is a sub-class of ModelElement.

The association end has no direct access on any diagram for binary associations. The ends of an N-ary association may be selected by clicking on the line in the diagram. The stereotype, name and multiplicity are shown at the relevant end of the parent association (see Figure 17.1, “Possible artifacts on a use case diagram.”). Where shared or composite aggregation is selected for one association end, the opposite end is shown as a solid diamond (composite aggregation) or hollow diamond (shared aggregation).

**Tip**

Although you can change attributes of association ends when creating a use case model, this is often not necessary. Many of the properties of an association end relate to its use in class diagrams, and are of limited relevance to use cases. The most useful attributes to consider altering are the name (used as the role name) and the multiplicity.

**Note**
ArgoUML does not currently support showing qualifiers on the diagram, as described in the UML 1.3 standard.

18.12.1. Association End Details Tabs

The details tabs that are active for associations are as follows.

ToDoItem
Standard tab.

Properties

Documentation
Standard tab. See Section 13.4, “Documentation Tab”.

Presentation
Standard tab.

Source
Standard tab. This tab contains a declaration for the association end as an instance of the artifact to which it is connected.

Tagged Values
Standard tab. In the UML metamodel, AssociationEnd has the following standard tagged values defined.

- derived (from the superclass, ModelElement). Values true, meaning the association end is redundant??it can be formally derived from other elements, or false meaning it cannot.

Tip
Derived association ends still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation. However the tag only makes sense for an association end if it is also applied to the parent association.

Note
The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML

18.12.2. Association End Property Toolbar

Go up
Navigate up to the association to which this end belongs.

Go Opposite
This navigates to the other end of the association.

**New Qualifier**

This creates a new Qualifier for the selected association-end, navigating immediately to the properties tab for that qualifier.

**Warning**

Qualifiers are only partly supported in ArgoUML V0.18. Hence, activating this button creates a qualifier in the model, which is not shown on the diagram. Also, the properties panel for a qualifier equals that of a regular attribute.

**New Stereotype**

This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected association-end, navigating immediately to the properties tab for that stereotype.

**Delete**

This deletes the selected association-end from the model.

**Note**

This button is downlighted for binary associations, since an association needs at least two ends. Only for N-ary associations, this button is accessible, and deletes just one end from the association.

### 18.12.3. Property Fields For Association End

**Name**

Text box. The name of the association end, which provides a *role name* for this end of the association. This role name can be used for navigation, and in an implementation context, provides a name by which the source end of an association can reference the target end.

**Note**

ArgoUML does not enforce any naming convention for association ends.

**Stereotype**

Drop down selector. Association end is provided by default with the UML standard stereotypes for AssociationEnd (association, global, local, parameter, self).

**Navigate Stereotype**

Icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Association**

Text box. Records the parent association for this association end. Button 1 double click on this entry will navigate to that association.

**Type**
Drop down selector providing access to all standard UML types provided by ArgoUML and all new classes created within the current model.

This is the type of the entity attached to this end of the association.

**Tip**

By default ArgoUML will select the class of the artifact to which the link end is connected. However, an association can be moved to another class by selecting another entry here.

**Multiplicity**

Drop down menu with edit box. The value can be chosen from the drop down box, or a new one can be edited in the text box. Records the multiplicity of this association end (with respect to the other end), i.e. how many instances of this end may be associated with an instance of the other end. The multiplicity is shown on the diagram at that end of the association.

**Modifiers**

There are 3 modifiers: navigable, ordered and static. All 3 are checkboxes.

- **navigable**. Indicates that this end can be navigated to from the other end.

**Note**

The UML 1.4 standard provides a number of options for how navigation is displayed on an association end. ArgoUML uses option 3, which means that arrow heads are shown at the end of an association, when navigation is enabled at only one end, to indicate the direction in which navigation is possible. This means that the default, with both ends navigable has no arrows.

- **ordered**. When placed on one end, specifies whether the set of links from the other instance to this instance is ordered. The ordering must be determined and maintained by Operations that add links. It represents additional information not inherent in the objects or links themselves. Possibilities for the checkbox are: Unchecked - The links form a set with no inherent ordering. Checked - A set of ordered links can be scanned in order.

- **Static**. (To be written)

**Specification**

List. Designates zero or more Classifiers that specify the Operations that may be applied to an Instance accessed by the AssociationEnd across the Association. These determine the minimum interface that must be realized by the actual Classifier attached to the end to support the intent of the Association. May be an Interface or another Classifier. The type of classifier is indicated by an icon.

Button 1 double click navigates to the selected classifier, button 2 click brings a pop up menu with one entry.

- **Add**. Add a new specification classifier. This opens the *Add/Remove Specifications* dialog box (see figure below), which allows choosing between all possible classifiers, and adding or removing them to the selected list.

**Figure 18.4. The “Add/Remove Specifications” dialog box**
Qualifiers

Text box. Records the qualifiers for this association end. Button 1 double click on this entry will navigate to that qualifier. Button 2 click will show a popup menu containing two items: Move Up and Move Down, which allow reordering the qualifiers.

Aggregation

Radio box, with three entries composite, none and aggregate. Indicates whether the relationship with the far end represents some type of loose whole-part relationship (aggregation) or tight whole-part relationship (composite).

Shared aggregation is shown by a hollow diamond at the “whole” end of the association. Composite aggregation is shown by a solid diamond.

Note

You may not have aggregation at both ends of an association. ArgoUML does not enforce this constraint.

The “whole” end of a composite aggregation should have a multiplicity of one. ArgoUML does not enforce this constraint.

Changeability

Radio box, with three entries add only, changeable and frozen. Indicates whether instances of this end of the association-end may be: i) created but not deleted after the target instance is created; ii) created and deleted by the source after the target instance is created; or iii) not created or deleted by the source after the target instance is created.

Visibility

Radio box, with four entries public, private, protected, and package. Indicates whether navigation to this end may be by: i) any classifier; ii) only by the source classifier; or iii) only the source classifier and its children.

18.13. Dependency

Dependency is a relationship between two artifacts showing that one depends on the other.

Within the UML metamodel, Dependency is a sub-class of Relationship.

Dependency is represented as a dashed line with an open arrow head from the depending artifact to that which it is dependent upon.

18.13.1. Dependency Details Tabs

The details tabs that are active for dependencies are as follows.

ToDoItem

Standard tab.

Properties

18.13.2. Dependency Property Toolbar

Go up
Navigate up through the package structure of the model. For a dependency this will be the package containing the dependency.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected dependency, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the selected dependency from the model.

Warning
This is a deletion from the model not just the diagram. To delete a dependency from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

18.13.3. Property Fields For Dependency

Name
Text box. The name of the dependency.
**Tip**

It is quite common to leave dependencies unnamed.

**Note**

ArgoUML does not enforce any naming convention for associations.

**Note**

There is no representation of the name of a dependency on the diagram.

**Stereotype**

Drop down selector. Dependency has no standard stereotypes of its own under UML 1.3. and so ArgoUML does not provide any. The stereotype is shown between ?? and ?? above or across the generalization.

**Navigate Stereotype**

Icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Namespace**

Text box. Records the namespace for the dependency. This is the package hierarchy.

**Suppliers**

Text area. Lists the end of the relationship that is supplying what is needed by the other end.

Button 1 double click on a supplier will navigate to that element.

**Clients**

Text area. Lists the “depending” ends of the relationship, i.e. the end that makes use of the other end.

Button 1 double click on a client will navigate to that element.

**18.14. Generalization**

Generalization is described under use case diagrams (see Section 17.8, “Generalization”).

**Note**

Within the context of classes, generalization and specialization are the UML terms describing class inheritance.

**18.15. Interface**

An interface is a set of operations characterizing the behavior of an element. It can be usefully thought
of as an abstract class with no attributes and no non-abstract operations. In the UML metamodel it is a sub-class of Classifier and through that GeneralizableElement.

An interface is represented on a class diagram as a rectangle with two horizontal compartments. The top compartment displays the interface name (and above it ??interface??) and the second any operations. Just like a class, the operations compartment can be hidden.

### 18.15.1. Interface Details Tabs

The details tabs that are active for interfaces are as follows.

- **ToDoItem**
  - Standard tab.

- **Properties**
  - See Section 18.15.2, “Interface Property Toolbar” and Section 18.15.3, “Property Fields For Interface” below.

- **Documentation**
  - Standard tab. See Section 13.4, “Documentation Tab”.

- **Presentation**
  - Standard tab. The tick box Display Operations allows the operation compartment to be shown (the default) or hidden. This is a setting valid for only the current diagram. The Bounds: field defines the bounding box for the package on the diagram.

- **Source**
  - Standard tab. This contains a template for the interface declaration and declarations of associated interfaces.

- **Tagged Values**
  - Standard tab. In the UML metamodel, Interface has the following standard tagged values defined.

  - **persistence** (from the superclass, Classifier). Values transitory, indicating state is destroyed when an instance is destroyed or persistent, marking state is preserved when an instance is destroyed.

  **Warning**

  Since interfaces are by definition abstract, they can have no instance, and so this tagged value must refer to the properties of the realizing class.

  - **semantics** (from the superclass, Classifier). The value is a specification of the semantics of the interface.

  - **derived** (from the superclass, ModelElement). Values true, meaning the interface is redundant and can be formally derived from other elements, or false meaning it cannot.

  **Note**

  Derived interfaces still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.
Note

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

Checklist
Standard tab for an Interface.

18.15.2. Interface Property Toolbar

Go up
Navigate up through the package structure.

New operation
This creates a new operation (see Section 18.7, “Operation”) within the interface, navigating immediately to the properties tab for that operation.

New reception
This creates a new reception, navigating immediately to the properties tab for that reception.

New interface
This creates a new interface in the same namespace as the selected interface, navigating immediately to the properties tab for the new interface.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected interface, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the interface from the model.

Warning
This is a deletion from the model not just the diagram. To delete an interface from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

18.15.3. Property Fields For Interface

Name
Text box. The name of the interface. The name of an interface has a leading capital letter, with words separated by “bumpy caps”.

Note
Unlike classes, the ArgoUML critics will not complain about interface names that do not have an initial capital.
Stereotype
Drop down selector. Interface is provided by default with the UML standard stereotypes for the par-
et meta-class, Classifier (metaclass, powertype, process, thread and utility).

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Sec-

Namespace
Drop down selector. Records and allows changing the namespace for the interface. This is the pack-
age hierarchy.

Modifiers
Check box, with entries Abstract, Leaf and Root.

• Abstract is used to declare that this interface cannot be instantiated, but must always be spe-
cialized. The name of an abstract interface is displayed in italics on the diagram.

Caution
This is meaningless, since by definition an interface is an abstract entity. The
UML 1.3 standard offers no clarification.

• Leaf indicates that this interface cannot be further specialized, while Root indicates it can have
no generalizations.

Visibility
Radio box, with three entries public, protected, private and package. Indicates whether
navigation to this end may be by: i) any classifier; ii) only the source classifier and its children; or
iii) only by the source classifier.

Generalizations
Text area. Lists any interface that generalizes this interface.

Button 1 double click navigates to the generalization and opens its property tab.

Specializations
Text box. Lists any specialized interface (i.e. for which this interface is a generalization.

Button 1 double click navigates to the generalization and opens its property tab.

AssociationEnds
Text box. Lists any AssociationEnds (see Section 18.12, “Association End”) connected to this inter-
face.

Note
Associations between classes and interfaces must be navigable only from the class to
the interface. ArgoUML will create associations between classes and interfaces with
the correct navigability, but does not prevent the user from altering this.

Button 1 double click navigates to the selected entry.

Operations
Text area. Lists all the operations (see Section 18.7, “Operation”) defined on this interface. Button 1
double click navigates to the selected operation. Button 2 click will show a popup menu with two
items: **Move Up** and **Move Down**, which allow reordering the operations.

**Caution**

All operations on an interface *must* be public. The ArgoUML critics will complain if this is not the case.

### 18.16. Abstraction

An abstraction is a dependency relationship joining two artifacts within the model at different levels of abstraction. Within ArgoUML it is principally used through its specific stereotype `realize` to define realization dependencies, which link artifacts that *specify* behavior to the corresponding artifacts that *implement* the behavior.

In the UML metamodel **Abstraction** is a sub-class of **Dependency** and through that **Relationship**.

An abstraction with stereotype `realize` is represented on a class diagram as a dotted line with a solid white head at the specifying end.

**Caution**

All other stereotypes of abstraction should be represented using an open arrow head, but this is not supported by ArgoUML.

### 18.16.1. Abstraction Details Tabs

The details tabs that are active for abstractions are as follows.

**ToDoItem**

Standard tab.

**Properties**

See Section 18.16.2, “Abstraction Property Toolbar” and Section 18.16.3, “Property Fields For Abstraction” below.

**Documentation**

Standard tab. See Section 13.4, “Documentation Tab”.

**Presentation**

Standard tab.

**Note**

The values for the bounds of the abstraction are downlighted, since the association is tied to particular artifacts.

**Source**

Standard tab. This contains the single downlighted text N/A.

**Tagged Values**

Standard tab. In the UML metamodel, **Abstraction** has the following standard tagged values
• **derived** (from the superclass, `ModelElement`). Values `true`, meaning the abstraction is redundant (it can be formally derived from other elements, or `false` meaning it cannot.

**Note**

Derived abstractions still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

**Note**

The UML `Element` metaclass from which all other artifacts are derived includes the tagged element `documentation` which is handled by the `documentation tab` under ArgoUML.

### 18.16.2. Abstraction Property Toolbar

**Go up**

Navigate up through the package structure.

**Delete**

This deletes the abstraction from the model.

**Warning**

This is a deletion from the model *not* just the diagram. To delete an abstraction from the diagram, but keep it within the model, use the main menu `Remove From Diagram` (or press the Delete key).

### 18.16.3. Property Fields For Abstraction

**Name**

Text box. The name of the abstraction. There are no constraints on the name of an abstraction, which is not shown on any diagram.

**Stereotype**

Drop down selector. Abstraction is provided by default with the UML standard stereotypes `derive`, `realize`, `refine` and `trace`.

**Caution**

ArgoUML automatically selects the stereotype `realize` when an abstraction is created. The user is free to change the stereotype to use the abstraction to indicate for example a `trace` relationship. However ArgoUML will not alter the representation on the diagram accordingly.

**Navigate Stereotype**

Icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Sec-

Namespace
Drop down selector. Records and allows changing the namespace for the abstraction. This is the package hierarchy.

Suppliers
Text area. Lists the artifact that is the supplier end of this abstraction (for a realization this is the end providing the implementation).

Note
Although this is a text area there is no mechanism for adding more than one supplier.

Button 1 double click navigates to the selected entry.

Clients
Text area. Lists the artifact that is the client end of this abstraction (for a realization this is the end providing the specification).

Note
Although this is a text area there is no mechanism for adding more than one client.

Button 1 double click navigates to the selected entry.
Chapter 19. Sequence Diagram Artifact Reference

19.1. Introduction

This chapter describes each artifact that can be created within a sequence diagram. Note that some sub-artifacts of artifacts on the diagram may not actually themselves appear on the diagram.

There is a close relationship between this material and the Properties tab of the details pane (see Section 13.3, “Properties Tab”). That section covers properties in general, in this chapter they are linked to specific artifacts.

**Caution**

Sequence diagrams are not fully developed yet in ArgoUML. Many aspects are not fully implemented, or may not behave as expected.

Figure 19.1, “Possible artifacts on a sequence diagram.” shows a sequence diagram with all possible artifacts displayed.

**Figure 19.1. Possible artifacts on a sequence diagram.**

19.1.1. Limitations Concerning Sequence Diagrams in ArgoUML

The sequence diagram is still rather under-developed in ArgoUML.

The biggest difficulties are with the actions behind the stimuli. These are purely textual in implementation, and there is no way to link them back to their associated operations or signals.

19.2. Object

An object is an instance of a class. In the UML metamodel Object is a sub-class of Instance. Within a sequence diagram objects may be used to represent a specific instance of a class. Unlike collaboration diagrams (see Chapter 21, Collaboration Diagram Artifact Reference), sequence diagrams cannot show generic behavior between classifier roles.

An object is represented on a sequence diagram in ArgoUML as a plain box labeled with the object name (if any) and class name, separated by a colon (:). As links with stimuli to and from other objects are added, a time line grows down from the object. This is thin where the object does not have control and thick where it does.

**Caution**

The current release of ArgoUML shows interactions between objects, although the UML standard for sequence diagrams is for interaction between instances of any classifier).

However the actual implementation in ArgoUML permits any classifier to be used with the
object, and so the diagram can successfully represent instances of actors for example as well as classes.

### 19.2.1. Object Details Tabs

The details tabs that are active for objects are as follows.

**ToDoItem**  
Standard tab.

**Properties**  
See Section 19.2.2, “Object Property Toolbar” and Section 19.2.3, “Property Fields For Object” below.

**Documentation**  
Standard tab.

**Presentation**  
Standard tab. The values for the bounds of the object notionally define the bounding box of the object and its time line. However if you change them it will have no effect, and the original values will be reset when you next revisit the tab.

**Source**  
Standard tab, but with no contents.

**Caution**

An object should not generate any code, so having this tab active is probably a mistake.

**Tagged Values**  
Standard tab. In the UML metamodel, Object has the following standard tagged values defined.

- **persistence** (from the superclass, Instance). Showing the permanence of the state information associated with the object. Values transitory (state is destroyed when the object is destroyed) and persistent (state is preserved when the object is destroyed).

- **derived** (from the superclass, ModelElement). Values true, meaning the object is redundant? it can be formally derived from other elements, or false meaning it cannot.

**Note**

Derived objects still have their value in analysis and design to introduce useful names or concepts, and in design to avoid re-computation.

**Note**

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.
Standard tab for a Classifier.

### 19.2.2. Object Property Toolbar

Go up
Navigate up through the package structure.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected object, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the object from the model

**Warning**
This is a deletion from the model *not* just the diagram. To delete an object from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

### 19.2.3. Property Fields For Object

**Name**
Text box. The name of the object. By convention object names start with a lower case letter and use bumpy caps to divide words within the name.

**Note**
ArgoUML does not enforce this naming convention.

**Stereotype**
Drop down selector. Object has no stereotypes by default in the UML standard.

**Navigate Stereotype**
Icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 18.4, “Stereotype”).

**Namespace**
Text box. Records the namespace for the object. This is the package hierarchy.

**Stimuli Sent**
Text area. Lists the stimuli sent to this object.

**Stimuli Received**
Text area. Lists the stimuli received by this object.

**Classifier**
Drop down selector. The name of the classifier of which this is an object.

**Caution**
In the current release of ArgoUML the drop down selector will include all classifiers (i.e. interfaces, actors, use cases and datatypes as well), which is what is wanted on the diagram, although it should properly be called an instance, rather than an object. In practice only instances of classes and actors make much sense.

**Note**

In the current release of ArgoUML the same graphical presentation is used, even if the object is actually representing an instance of an actor (when a stick-man would be more usual).

### 19.3. Stimulus

A stimulus is a communication between two instances and is generated by an action. On a sequence diagram a stimulus is associated with a link—an instance of an association linking two object instances. In the UML metamodel **Stimulus** is a sub-class of **ModelElement**.

The link (see Section 19.9, “Link”) associated with a stimulus is represented on a sequence diagram in ArgoUML as an arrow between the time lines of the object instances (or the object head in the case of stimulus create, described below) labeled with the name of the action (if any), and the action, separated by a colon (:). The type of line and arrowhead depends on the type of action that generated the stimulus:

- **Stimulus Call**. Generated by a call action, itself the result of an operation of a class. Shown as a solid line with a solid arrowhead to the time line of the object instance receiving the stimulus.

- **Stimulus Create**. Generated by a create action for the class for which an instance is to be created. Shown as a solid line with a solid arrowhead to the object head of the object instance being created.

- **Stimulus Destroy**. Generated by a destroy action of the originating object. Shown as a solid line with an open arrowhead terminating in a diagonal cross at the end of the time line of the receiving (destroyed) object instance.

- **Stimulus Send**. Generated by a send action, the result of a signal raised by an operation of the sending object instance and handled by the receiving object instance. Shown as a solid line with half an open arrowhead.

- **Stimulus Return**. Generated by an object instance that has received an earlier call stimulus and is returning a result to the calling object instance. Shown as a dotted line with an open arrowhead.

**Note**

ArgoUML does not allow you to create stimuli directly, but instead provides tools to create stimuli of each of the five types above.

**Caution**

In the current release of ArgoUML, there is no way to show a terminate action where an object instance destroys itself. One way is to draw a destroy action that loops back to the object itself, give it an action with no name and use the style tab to set an invisible line, but
this still leaves the arrow head showing, which is unsightly. It is also semantically incor-
rect anyway to use a destroy action to represent a terminate action.

19.3.1. Stimulus Details Tabs

The details tabs that are active for stimuli are as follows.

ToDoItem
Standard tab.

Properties
See Section 19.3.2, “Stimulus Property Toolbar” and Section 19.3.3, “Property Fields For Stimulus” below.

Documentation
Standard tab.

Style
Standard tab. The values for the bounds of the stimulus notionally define the bounding box of the stimulus and its time line. However if you change them it will have no effect, and the original values will be reset when you next revisit the tab.

Altering the Fill and Shadow entries has no effect. Rather bizarrely you can set the Line entry and it will draw a line around the signal, which is not a standard UML representation.

Tip
To change the color of the line, you should select the associated link (click on it a little way from the stimulus) and use its style tab (see Section 19.9, “Link”).

Caution
In the current release of ArgoUML changing the values of the Bounds field is possible, but will make only a temporary change to the position of the stimulus. Selecting any artifact on the screen causes the stimulus to return to its original position and the original values to be restored.

Source
Standard tab, but with no contents.

Caution
A stimulus should not generate any code, so having this tab active is probably a mis-
take.

Constraints
Standard tab. ArgoUML only supports constraints on Classes and Features (Attributes, Operations, Receptions, and Methods), so this tab is grayed out.

Tagged Values
Standard tab. In the UML metamodel, Stimulus has the following standard tagged values defined.
• derived (from the superclass, ModelElement). Values true, meaning the stimulus is redundant??it can be formally derived from other elements, or false meaning it cannot.

Note

Derived stimuli still have their value in analysis and design to introduce useful names or concepts, and in design to avoid re-computation.

Note

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

19.3.2. Stimulus Property Toolbar

Go up
Navigate up through the package structure.

Delete
This deletes the stimulus from the model

Warning

This is a deletion from the model not just the diagram. To delete an stimulus from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

19.3.3. Property Fields For Stimulus

Name
Text box. There is no convention for naming stimuli, and it is quite normal to leave them unnamed. The action is sufficient identification.

Tip

It is sometimes useful to give simple names to stimuli, so they can be referred to in attached notes giving timing constraints.

Action
Text box. This is used to identify the action that generated the stimulus.

Caution

The current release of ArgoUML only implements actions as textual descriptions.

As a practical convention it is suggested that call actions are shown as the name of the operation generating the action with any arguments in parentheses and that send ac-
tions are shown as the name of the signal generating the action with any arguments in parentheses. Return actions should be shown as the expression for the value they return, or empty otherwise. Create and destroy actions should be left empty, since they are implied by their representation.

**Stereotype**
Drop down selector. Stimulus has no stereotypes by default in the UML standard, but ArgoUML provides the stereotypes, machine, organization and person.

**Caution**
ArgoUML also provides the stereotype realize for stimuli. This appears to be an error, since this stereotype properly belongs to the Abstraction metaclass.

**Navigate Stereotype**
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 18.4, “Stereotype”).

**Sender**
Text box. Identifies the instance which sent this stimulus.

- Button 1 click navigates to the sender instance, button 2 gives a pop up menu with one entry.
- Open. Navigate to the selected sender instance.

**Receiver**
Text box. Identifies the instance which receives this stimulus.

- Button 1 click navigates to the receiver instance, button 2 gives a pop up menu with one entry.
- Open. Navigate to the selected receiver instance.

**Warning**
In the current release of ArgoUML this field is broken. It always shows the entry none and the pop-up menu is grayed out.

**Namespace**
Text box. Records the namespace for the stimulus. This is the package hierarchy.

- Button 1 click on the entry will navigate to the package defining this namespace (or the model for the top level namespace).

### 19.4. Stimulus Call

This tool creates a stimulus associated with a call action on the diagram, creating at the same time the associated link between sender and receiving instances.

All details tabs and properties are identical to that of stimulus in general (see Section 19.3, “Stimulus”). Its graphical representation on the diagram is that of a stimulus associated with a call action, i.e. a solid line with a solid arrow head.
Note
Because the current release of ArgoUML does not fully implement actions, there is no enforcement of the relationship to a call action.

19.5. Stimulus Create
This tool creates a stimulus associated with a create action on the diagram, creating at the same time the associated link between sender and receiving instances.

All details tabs and properties are identical to that of stimulus in general (see Section 19.3, “Stimulus”). Its graphical representation on the diagram is that of a stimulus associated with a create action, i.e. a solid line with a solid arrow head terminating at the head of the created instance.

Note
Because the current release of ArgoUML does not fully implement actions, there is no enforcement of the relationship to a create action.

19.6. Stimulus Destroy
This tool creates a stimulus associated with a destroy action on the diagram, creating at the same time the associated link between sender and receiving instances.

All details tabs and properties are identical to that of stimulus in general (see Section 19.3, “Stimulus”). Its graphical representation on the diagram is that of a stimulus associated with a destroy action, i.e. a solid line with an open arrow head terminating at a cross at the bottom of the destroyed instance's time line.

Note
Because the current release of ArgoUML does not fully implement actions, there is no enforcement of the relationship to a destroy action.

19.7. Stimulus Send
This tool creates a stimulus associated with a send action on the diagram, creating at the same time the associated link between sender and receiving instances.

All details tabs and properties are identical to that of stimulus in general (see Section 19.3, “Stimulus”). Its graphical representation on the diagram is that of a stimulus associated with a send action, i.e. a solid line with half an open arrow head.

Note
Because the current release of ArgoUML does not fully implement actions, there is no enforcement of the relationship to a send action.

19.8. Stimulus Return
This tool creates a stimulus associated with a return action on the diagram, creating at the same time the associated link between sender and receiving instances.

All details tabs and properties are identical to that of stimulus in general (see Section 19.3, “Stimulus”). Its graphical representation on the diagram is that of a stimulus associated with a return action, i.e. a dotted line with an open arrow head.

**Note**

Because the current release of ArgoUML does not fully implement actions, there is no enforcement of the relationship to a return action.

### 19.9. Link

A link is an instance of an association. In the UML metamodel Link is a sub-class of Instance. Within a sequence diagram links are created indirectly when an associated stimulus is created.

An link is represented on a sequence diagram in ArgoUML as a line connecting the instances concerned. However on a sequence diagram the representation is modified to reflect the type of action associated with the stimulus carried on the link (see Section 19.3, “Stimulus”).

#### 19.9.1. Link Details Tabs

The details tabs that are active for links are as follows.

- **ToDoItem**
  - Standard tab.

- **Properties**

- **Documentation**
  - Standard tab.

- **Presentation**
  - Standard tab. The values for the bounds of the link are downlighted, since they are determined by the objects connected.

- **Source**
  - Standard tab, but with no contents.

  **Caution**

  A link should not generate any code, so having this tab active is probably a mistake.

- **Tagged Values**
  - Standard tab. In the UML metamodel, Link has the following standard tagged values defined.
    - **persistence** (from the superclass, Instance). Showing the permanence of the state information associated with the link. Values transitory (state is destroyed when the link is destroyed) and persistent (state is preserved when the link is destroyed).
    - **derived** (from the superclass, ModelElement). Values true, meaning the link is redundant??it can be formally derived from other elements, or false meaning it cannot.
Note

Derived links still have their value in analysis and design to introduce useful names or concepts, and in design to avoid re-computation.

Note

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

Checklist
Standard tab for a Classifier.

19.9.2. Link Property Toolbar

Go up
Navigate up through the package structure.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected link, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the link from the model

Warning
This is a deletion from the model not just the diagram. To delete an link from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

19.9.3. Property Fields For Link

Name
Text box. The name of the link. By convention link names start with a lower case letter and use bumpy caps to divide words within the name.

Note
ArgoUML does not enforce this naming convention.

Stereotype
Drop down selector. Link has no stereotypes by default in the UML standard.

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Sec-
tion 18.4, “Stereotype”).

**Namespace**
- Text box. Records the namespace for the link. This is the package hierarchy.

**Connections**
- List box. Lists the connections of the link, i.e. the link-ends.

  Button 1 double click on the entry will navigate to the link-end.
Chapter 20. Statechart Diagram Artifact Reference

20.1. Introduction

This chapter describes each artifact that can be created within a statechart diagram. Note that some sub-artifacts of artifacts on the diagram may not actually themselves appear on the diagram.

There is a close relationship between this material and the Properties Tab of the Details Pane (see Section 13.3, "Properties Tab"). That section covers Properties in general, in this chapter they are linked to specific artifacts.

Figure 20.1, “Statechart diagram artifacts 1.” and Figure 20.2, “Statechart diagram artifacts 2.” show statechart diagrams with most possible artifacts displayed.

20.1.1. Limitations Concerning Statechart Diagrams in ArgoUML

The statechart diagrams support the 7 action types defined (CallAction, CreateAction, DestroyAction, ReturnAction, SendAction, TerminateAction and UninterpretedAction), but there is no way to use the same action more than once. Also, in a few cases, it is not possible to set or select the related elements; e.g. there is no way to select a signal for a SendAction.

Code generation from statechart diagrams is not developed yet.

20.2. State

A state models a situation during which some (usually implicit) invariant condition holds for the parent class. This invariant may be a static situation such as an object waiting for some external event to occur, or some dynamic activity “in progress”.

A state is represented on a statechart diagram in ArgoUML as a rectangle with rounded corners, with a horizontal line separating the name at the top from the description of the behavior below. The description of the behavior includes the entry and exit actions and any internal transitions.

20.2.1. State Details Tabs

The details tabs that are active for states are as follows.

ToDoItem
  Standard tab.
Properties
See Section 20.2.2, “State Property Toolbar” and Section 20.2.3, “Property Fields For State” below.

Documentation
Standard tab.

Presentation
Standard tab. The values for the bounds of the state define the bounding box of the state.

Stereotype
Standard tab.

Tagged Values
Standard tab.

20.2.2. State Property Toolbar

Go up
Navigate up through the package structure.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected state, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the state from the model

Note
This is a deletion from the model, not just the diagram. You can not just remove a state from the diagram, and keep it within the model, as is possible in other diagrams.

20.2.3. Property Fields For State

Name
Text box. The name of the state. By convention state names start with a lower case letter and use bumpy caps to divide words within the name.

Note
ArgoUML does not enforce this naming convention.

Container
Text box. Shows the container of the state. This is the state hierarchy.

Button 1 double click on the entry will navigate to the composite state that contains this state. All states are at least contained by the otherwise hidden top-level state (named “top”) that is the root of the state containment hierarchy.

Entry-Action
Text box. Shows the name of the action (if any) to be executed on entry to this state.

**Note**

This field shows the name of the action, while on the diagram the expression of the action is shown.

Button 1 double-click navigates to the selected entry, button 2 gives a pop up menu with two entries:

- **New**. Add a new Entry action of a certain kind. This menu has the following submenus to select the kind of action: Call Action, Create Action, Destroy Action, Return Action, Send Action, Terminate Action, Uninterpreted Action.

- **Delete From Model**. Delete the Entry-Action.

**Exit-Action**

Text box. Shows the action (if any) to be executed on exit from this state.

Button 1 click navigates to the selected action, button 2 gives a pop up menu with two entries.

- **New**. Add a new Exit action of a certain kind. This menu has the following submenus to select the kind of action: Call Action, Create Action, Destroy Action, Return Action, Send Action, Terminate Action, Uninterpreted Action.

- **Delete From Model**. Delete the Exit-Action.

**Do-Activity**

Text box. Shows the action (if any) to be executed while being in this state.

Button 1 click navigates to the selected action, button 2 gives a pop up menu with two entries.

- **New**. Add a new Do-Activity (action) of a certain kind. This menu has the following submenus to select the kind of action: Call Action, Create Action, Destroy Action, Return Action, Send Action, Terminate Action, Uninterpreted Action.

- **Delete From Model**. Delete the Do-Activity.

**Deferrable Events**

Text box. Shows a list of events that are candidates to be retained by the state machine if they trigger no transitions out of the state (not consumed).

Button 1 click navigates to the selected event, button 2 on an event gives a pop up menu with the following entries.

- **Select**. Allows to add already existing events to the list of deferred ones.

- **New**. Add a new event of a certain kind. This menu has the following submenus to select the kind of event: Call Event, Change Event, Signal Event, Time Event.

- **Delete From Model**. Delete the event.

**Incoming**

Text area. Lists all the transitions that enter this state.

Button 1 double click navigates to the selected entry.

**Outgoing**

Text area. Lists all the transitions that leave this state.
Button 1 double click navigates to the selected action.

**Internal Transitions**

Text area. Lists all the internal transitions of the state. Such transitions neither exit nor enter the state, so they do not cause a state change. Which means that the Entry and Exit actions are not invoked.

**Note**

This field shows the name of the transition, while on the diagram the name of the trigger is shown, separated with a / from the effect script.

Button 1 double-click navigates to the selected transition, button 2 gives a pop up menu with one entry.

- New. Add a new internal transition.

### 20.3. Action

An action specifies an executable statement and is an abstraction of a computational procedure that can change the state of the model. In the UML metamodel it is a child of ModelElement. Since in the metamodel an ActionSequence is itself an Action that is an aggregation of other actions (i.e. the "composite" pattern), an ActionSequence may be used anywhere an action may be.

There are a number of different types of action that are children of Action within the UML metamodel.

- **CreateAction.** Associated with a classifier, this action creates an instance of that classifier.
- **CallAction.** Associated with an operation, this action calls the given operation.
- **ReturnAction.** An action used to return a result to an earlier caller.
- **SendAction.** Associated with a signal, this action causes the signal to be raised.
- **TerminateAction.** Causes the invoking object to self-destruct.
- **UninterpretedAction.** An action used to specify language-specific actions that do not classify under the other types of actions.
- **DestroyAction.** Destroys the specified target object.

An action is represented on the diagram by the text of its expression.

**Caution**

The V0.20 release of ArgoUML only partially implements actions. As a practical convention it is suggested that call actions are shown as the name of the operation generating the action with any arguments in parentheses and that send actions are shown as the name of the signal generating the action with any arguments in parentheses. Return actions should be shown as the expression for the value they return, or empty otherwise. Create and destroy actions should shown as create(<target>) and destroy(<target>). Terminate action should be shown as terminate.
20.3.1. Action Details Tabs

The details tabs that are active for actions are as follows.

**ToDoItem**
- Standard tab.

**Properties**
- See Section 20.3.2, “Action Property Toolbar” and Section 20.3.3, “Property Fields For Action” below.

**Documentation**
- Standard tab.

**Stereotype**
- Standard tab. In the UML metamodel, *Action* has no standard stereotypes defined.

**Tagged Values**
- Standard tab. In the UML metamodel, *Action* has no standard tagged value defined.

20.3.2. Action Property Toolbar

**Go up**
- Navigate up through the hierarchical structure.

**New Stereotype**
- This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected action, navigating immediately to the properties tab for that stereotype.

**Delete**
- This deletes the Action from the model.

20.3.3. Property Fields For Action

**Name**
- Text box. The name of the action. By convention action names start with a lower case letter and use bumpy caps to divide words within the name.

  **Note**
  - ArgoUML does not enforce this naming convention.

**Asynchronous**
- Check box. Indicates if a dispatched Stimulus is asynchronous or not.

**Script**
- Double text box with the expression that defines the action. This field consists of two parts, the first one contains the body (script) of the expression, and the second one contains the particular programming language used to write the expression.

**Recurrence**
Double Text box. An expression stating how many times the Action should be performed. The field consists of two parts: the first one for the expression, the second one for the language it is written in.

Arguments
Text box. This is an ordered list with the arguments of the action.

Button 1 double-click on any of the arguments navigates to that argument, button 2 click brings up a pop up menu with two entries.

- New. Create a new argument and navigate to it.
- Remove. Deletes the argument from the model.

Instantiation (only for CreateAction)
Text box. This shows the classifier that gets instantiated by the create-action.

Button 1 double-click on the classifier navigates to that argument, button 2 click brings up a pop up menu with one entry.

- Add... This brings up a dialog box that allows selecting the one classifier that gets created.

20.4. Composite State

A composite state is a state that contains other states (known as sub-states), allowing hierarchical state machines to be constructed.

A composite state is represented on a statechart diagram in ArgoUML as a large rectangle with rounded corners, with a horizontal line separating the name at the top from the description of the behavior and the model of the sub-state machine below. The description of the behavior includes the entry, exit and do actions and any internal transitions.

Sub-states are placed within a composite machine by placing them entirely within the composite state. This can be done at creation time, i.e. when creating the state for the first time in the editing pane. Alternatively, an existing state can be dragged onto a composite state.

The description of a composite state is almost identical to that of a state (see Section 20.2, “State” and so is not duplicated here. The only differences is one additional tool, one missing field, and one additional field, which are described as follows.

New Concurrent Region
Adds a new concurrent region to the selected composite state.

Deferrable Events
This field is missing from V0.20 of ArgoUML.

Subvertices
Text area. Lists all the sub-states contained within this composite state.

Button 1 double-click navigates to the selected entry, button 2 gives a pop up menu with two entries.

- New. A submenu pops up, with a selection of 7 kinds of states, which can be added to the model. The 7 kinds of states supported are: Pseudo State, Synch State, Stub State, Composite State, Simple State, Final State, Submachine State.

Warning
Using this way of adding states to the model is not a good idea, since you will have to add the state to the diagram later. This can be done by selecting it in the explorer, and activating the pop-up menu, and selecting "Add to Diagram". It is advisable to use the toolbar of the diagram instead.

- **Delete From Model** Delete the selected state from the model.

## 20.5. Concurrent Region

A Concurrent Region is an “orthogonal conjunctive” component of a composite state, allowing concurrency to be constructed.

A concurrent region is represented on the diagram by a tile of a composite state, separated from other regions by a dashed line.

ArgoUML currently only supports a horizontal division of a concurrent composite state in regions.

The description of the details panels of a concurrent region is identical to that of a composite state (see Section 20.4, “Composite State” and so is not duplicated here.

## 20.6. Submachine State

A submachine state is a syntactical convenience that facilitates reuse and modularity. It is a shorthand that implies a macro-like expansion by another state machine and is semantically equivalent to a composite state. The state machine that is inserted is called the referenced state machine while the state machine that contains the submachine state is called the containing state machine. The same state machine may be referenced more than once in the context of a single containing state machine. In effect, a submachine state represents a call to a state machine subroutine with one or more entry and exit points. The entry and exit points are specified by stub states. SubmachineState is a child of State.

The submachine state is depicted as a normal state with the additional include declaration above (and separated by a line from) its internal transitions compartment. The expression following the include reserved word is the name of the invoked submachine.

ArgoUML currently only supports a horizontal division of a concurrent composite state in regions.

The description of the details panels of a concurrent region is almost identical to that of a composite state (see Section 20.4, “Composite State” and so is not duplicated here. The only difference is one additional field:

- **Submachine**
  - Drop-down selector. Allows selecting the submachine included within this composite state.

## 20.7. Stub State

A stub state only appears on a submachine state.

A submachine state represents the invocation of a state machine defined elsewhere. In the general case, an invoked state machine can be entered at any of its substates or through its default (initial) pseudostate. Similarly, it can be exited from any substate or as a result of the invoked state machine.
reaching its final state. The non-default entry and exits are specified through *stub states*. In the UML metamodel, StubState is a child of State.

Every Stub State has a label on the diagram, which corresponds to the pathname represented by the “Reference State” attribute of the stub state.

The description of the details panels of a stub state is almost identical to that of a pseudo state (see Section 20.11, “Pseudostate” and so is not duplicated here. The only difference is one additional field:

**Reference State**
Drop-down selector. Allows entering the path name of the reference state.

## 20.8. Transition

A transition is a directed relation between a source state (any kind, e.g. composite state) and a destination state (any kind, e.g. composite state). Within the UML metamodel, Transition is a sub-class of ModelElement.

A transition is represented on a statechart diagram in ArgoUML as a line with arrow connecting the source to the destination state. Next to this line is a string containing the following three parts: The trigger event (e.g. a Call Event), which may have parameters between brackets (()). Next follows (if any) the guard in square brackets ([ ]). Finally, if there is an effect (e.g. Call Action) defined, a slash (/) followed by the expression of the action.

### 20.8.1. Transition Details Tabs

The details tabs that are active for transitions are as follows.

- **ToDoItem**
  Standard tab.
- **Properties**
- **Documentation**
  Standard tab.
- **Presentation**
  Standard tab. The values for the bounds of the transition are downlighted, since the position of the transition is defined by its end points.
- **Stereotype**
  Standard tab. In the UML metamodel, Transition has no stereotypes defined by default.
- **Tagged Values**
  Standard tab. In the UML metamodel, Transition has no standard tagged values defined.
- **Checklist**
  Standard tab for a transition.

### 20.8.2. Transition Property Toolbar
Go up
   Navigate up in the hierarchy to the parent state machine.

New Stereotype
   This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected transition, navigating immediately to the properties tab for that stereotype.

Delete
   This deletes the transition from the model.

   **Warning**
   This is a deletion from the model *not* just the diagram. To delete a transition from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

### 20.8.3. Property Fields For Transition

**Name**
   Text box. The name of the transition. By convention transition names start with a lower case letter and use bumpy caps to divide words within the name.

   **Note**
   ArgoUML does not enforce this naming convention.

**StateMachine**
   Text box. Shows the name of the parent StateMachine for the transition.
   Button 1 double-click navigates to the StateMachine shown.

**State**
   Text box. Shows the name of the parent State in case of an internal transition.
   Button 1 double-click navigates to the State shown.

**Source**
   Text box. Shows the source state for the transition.
   Button 1 double-click navigates to the selected entry.

**Target**
   Text box. Shows the target state for the transition.
   Button 1 double-click navigates to the selected entry.

**Trigger**
   Text box. Shows the trigger event (if any) which invokes this transition.

   **Note**
   UML does not require there to be a trigger, e.g. when a guard is defined. In this case,
the transition is taken immediately if the guard is true.

Button 1 double-click navigates to the selected entry, button 2 gives a pop up menu with three entries.

- **Select** – Add.... This Add an existing trigger event. A sub-menu opens with 4 choices: Call Event, Change Event, Signal Event, Time Event.

- **Delete From Model**. Delete the trigger event from the model. This feature is always down-lighted in the current version of ArgoUML.

**Guard**
Text box. Shows the name of a guard (if any). The expression of a guard must be true before this transition can be taken.

Button 1 double-click navigates to the selected entry, button 2 gives a pop up menu with one entry.

- **New**. Add a new guard.

**Effect**
Text box. Shows the action (if any) to be invoked as this transition is taken.

Button 1 double-click navigates to the selected action, button 2 gives a pop up menu with two entries.

- **New**. Add a new Effect (action) of a certain kind. This menu has the following submenus to select the kind of action: Call Action, Create Action, Destroy Action, Return Action, Send Action, Terminate Action, Uninterpreted Action.

- **Delete From Model**. Delete the selected action from the model.

### 20.9. Event

An event is an observable occurrence. In the UML metamodel it is a child of ModelElement.

There are a number of different types of events that are children of event within the UML metamodel.

- **CallEvent**. Associated with an operation of a class, this event is caused by a call to the given operation. The expected effect is that the steps of the operation will be executed.

- **SignalEvent**. Associated with a signal, this event is caused by the signal being raised.

- **TimeEvent**. An event cause by expiration of a timing deadline.

- **ChangeEvent**. An event caused by a particular expression (of attributes and associations) becoming true.

An event is represented by its name.

#### 20.9.1. Event Details Tabs
The details tabs that are active for events are as follows.

**ToDoItem**
Standard tab.

**Properties**

**Documentation**
Standard tab.

**Stereotype**
Standard tab. In the UML metamodel, an Event has the following standard stereotypes defined.

- **create** (for a CallEvent only). Create is a stereotyped call event denoting that the instance receiving that event has just been created. For state machines, it triggers the initial transition at the topmost level of the state machine (and is the only kind of trigger that may be applied to an initial transition).

- **destroy** (for a CallEvent only). Destroy is a stereotyped call event denoting that the instance receiving the event is being destroyed.

**Tagged Values**
Standard tab. In the UML metamodel, an Event has no standard tagged values defined.

### 20.9.2. Event Property Toolbar

**Go up**
Navigate up through the composition structure.

**New Stereotype**
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected event, navigating immediately to the properties tab for that stereotype.

**New parameter**
This creates a new parameter for the event operation as the current parameter, navigating immediately to the properties tab for that parameter (see Section 18.8, “Parameter”).

**Delete**
This deletes the event from the model.

### 20.9.3. Property Fields For Event

**Name**
Text box. The name of the event. By convention event names start with a lower case letter and use bumpy caps to divide words within the name in the same way as operations.

**Note**
ArgoUML does not enforce this naming convention.
Tip

For call events it makes sense to use the name of the associated operation. For signal events it make sense to use the name of the signal, prefixed by \[\text{sig}\]. For time events use the time expression, prefixed by \[\text{time}\] and for change events the change expression, prefixed by \[\text{change}\].

Namespace
Text field. Shows the namespace for the event. This is the composition hierarchy.

Parameters
Text area, with entries for all the actual parameter values of the event (see Section 18.8, “Parameter”).

Button 1 double-click on any of the parameters navigates to that parameter, button 2 click brings up a pop up menu with one entry.

- **New Parameter.** Create a new parameter and navigate to it.

Transition
This shows the transition caused by the event.

Button 1 double-click on the transition navigates to that transition.

Operations
Drop-down selector. Only present for a Call Event. This allows specifying the operation that causes the event when called.

Signal
Text field. Only present for a Signal Event. This allows specifying the signal that causes the event when called.

Button 1 double-click navigates to the selected signal, button 2 gives a pop up menu with two entries.

- **Add...** This opens a dialog box that allows selecting an already existing signal.
- **New Signal.** Creates a new Signal, and navigates to it.

When
Double text field. Only present for a Time Event. This allows expressing the time that the event is called.

The first of the two fields is for the body of the expression, and the second one for the language in which it is written.

Warning

In ArgoUML V0.20, the properties panel of a change event lacks a field to enter the change expression.

20.10. Guard

A guard is associated with a transition. At the time an event is dispatched, the guard is evaluated, and if
false, its transition is disabled. In the UML metamodel, Guard is a child of ModelElement.

A guard is shown on the diagram by the text of its expression in square brackets ([ ]).

20.10.1. Guard Details Tabs

The details tabs that are active for guards are as follows.

ToDoItem
Standard tab.

Properties
See Section 20.10.2, “Guard Property Toolbar” and Section 20.10.3, “Property Fields For Guard” below.

Documentation
Standard tab.

Stereotype
Standard tab, containing the stereotypes for the guard. In the UML metamodel, Guard has no standard stereotypes defined.

Tagged Values
Standard tab. In the UML metamodel, Guard has no standard tagged values defined.

20.10.2. Guard Property Toolbar

Go up
Navigate up through the package structure.

New Stereotype
This creates a new Stereotype (see Section 16.5, "Stereotype") for the selected guard, navigating immediately to the properties tab for that stereotype.

Delete from Model
This deletes the guard from the model

Warning
This is a deletion from the model, not just the diagram.

20.10.3. Property Fields For Guard

Name
Text box. The name of the guard. By convention guard names start with a lower case letter and use bumpy caps to divide words within the name.

Note
ArgoUML does not enforce this naming convention.
20.11. Pseudostate

A pseudostate encompasses a number of different transient vertices on a state machine diagram. They are used, typically, to connect multiple transitions into more complex state transitions paths. For example, by combining a transition entering a fork pseudostate with a set of transitions exiting the fork pseudostate, we get a compound transition that leads to a set of concurrent target states. Pseudostates do not have the properties of a full state and serve only as a connection point for transactions (but with some semantic value). Within the UML metamodel, Pseudostate is a sub-class of StateVertex.

20.11.1. Pseudostate Details Tabs

The details tabs that are active for pseudostates are as follows.

ToDoItem
Standard tab.

Properties
See Section 20.11.2, “Pseudostate Property Toolbar” and Section 20.11.3, “Property Fields For Pseudostate” below.

Documentation
Standard tab.

Presentation
Standard tab.

Stereotype
Standard tab, containing the stereotypes of the pseudostate. In the UML metamodel, PseudoState has no standard stereotypes defined.

Tagged Values
Standard tab. In the UML metamodel, Pseudostate has no standard tagged values defined.

20.11.2. Pseudostate Property Toolbar
Go up
   Navigate up through the package structure.

New Stereotype
   This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected pseudostate, navigating immediately to the properties tab for that stereotype.

Delete from Model
   This deletes the pseudostate from the model

   Warning
   This is a deletion from the model not just the diagram.

20.11.3. Property Fields For Pseudostate

Name
   Text box. The name of the pseudostate. By convention pseudostate names start with a lower case letter and use bumpy caps to divide words within the name.

   Note
   ArgoUML does not enforce this naming convention.

   Tip
   Pseudostate names are not shown on the diagram and it is not usually necessary to give them a name.

Container
   Text box. Shows the container of the pseudostate. This is the state hierarchy.

   Button 1 double click on the entry will navigate to the composite state that contains this state (or the top-level state that is the root of the state containment hierarchy).

Incoming
   Text area. Lists any incoming transitions for the pseudostate.

   Button 1 double-click navigates to the selected transition.

Outgoing
   Text area. Lists any outgoing transitions for the pseudostate.

   Button 1 double-click navigates to the selected transition.

20.12. Initial State

The initial state is a pseudostate (see Section 20.11, “Pseudostate”) representing a source for a single transition to the default state of a composite state. It is the state from which any initial transition is made.
As a consequence it is not permissible to have incoming transitions. ArgoUML will not let you create such transitions, and if you import a model that has such transitions, a critic will complain.

There can be at most one initial pseudostate in a composite state, which must have (at most) one outgoing transition.

An initial state is represented on the diagram as a solid disc.

20.13. Final State

If a transition reaches a final state, it implies completion of the activity associated with that composite state, or at the top level, of the complete state machine. In the UML metamodel FinalState is a child of State.

Note

A final state is a true state (with all its attributes), not a pseudostate.

Completion at the top level implies termination (i.e. destruction) of the owning object instance.

The representation of a final state on the diagram is a circle with a small disc at its center.

20.13.1. Final State Details Tabs

The details tabs that are active for final states are as follows.

ToDoItem
  Standard tab.

Properties

Documentation
  Standard tab.

Presentation
  Standard tab.

Stereotype
  Standard tab, containing the stereotypes of the final state. In the UML metamodel, a FinalState has the no standard tagged values defined.

Tagged Values
  Standard tab. In the UML metamodel, FinalState has no standard tagged values defined.

20.13.2. Final State Property Toolbar

Go up
  Navigate up through the package structure.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected state, navigating immediately to the properties tab for that stereotype.

**Delete from Model**
This deletes the final state from the model

**Warning**
This is a deletion from the model *not* just the diagram.

### 20.13.3. Property Fields For Final State

**Name**
Text box. The name of the final state. By convention final state names start with a lower case letter and use bumpy caps to divide words within the name.

**Note**
ArgoUML does not enforce this naming convention.

**Tip**
Final state names are shown on the diagram but it is not usually necessary to give them a name.

**Container**
Text box. Shows the container of the final state. This is the state hierarchy.

Button 1 double click on the entry will navigate to the composite state that contains this state (or the top-level state that is the root of the state containment hierarchy).

**Entry-Action**
Text box. Shows the name of the action (if any) to be executed on entry to this final state.

Button 1 double-click navigates to the selected entry, button 2 gives a pop up menu with two entries:

- **New**. Add a new Entry action of a certain kind. This menu has the following 7 submenus to select the kind of action: Call Action, Create Action, Destroy Action, Return Action, Send Action, Terminate Action, Uninterpreted Action.

- **Delete From Model**. Delete the Entry-Action.

**Incoming**
Text area. Lists any incoming transitions for the final state.

Button 1 double-click navigates to the selected transition.

**Internal Transitions**
Text area. Lists all the internal transitions of the state. Such transitions neither exit nor enter the state, so they do not cause a state change. Which means that the Entry and Exit actions are not invoked.

Junction is a pseudostate (see Section 20.11, “Pseudostate”) which is used to split an incoming transition into multiple outgoing transition segments with different guard conditions. A Junction is also called a Merge or Static conditional branch. The chosen transition is that whose guard is true at the time of the transition.

A predefined guard denoted `else` may be defined for at most one outgoing transition. This transition is enabled if all the guards labeling the other transitions are false.

According the UML standard, its symbol is a small black circle. Alternatively, it may be represented by a diamond shape (in case of "Decision" for Activity diagrams). ArgoUML only represents a junction on the diagram as a solid (white by default) diamond, and does not support the black circle symbol for a junction.

20.15. Choice

Choice is a pseudostate (see Section 20.11, “Pseudostate”) which is used to split an incoming transition into multiple outgoing transition segments with different guard conditions. Hence, a Choice allows a dynamic choice of outgoing transitions. The chosen transition is that whose guard is true at the time of the transition (if more than one is true, one is selected at random).

A predefined guard denoted `else` may be defined for at most one outgoing transition. This transition is enabled if all the guards labeling the other transitions are false.

Note

This sort of pseudostate was formerly called a Branch by ArgoUML.

A choice is represented on the diagram as a small solid (white by default) circle (reminiscent of a small state icon).

20.16. Fork

Fork is a pseudostate (see Section 20.11, “Pseudostate”) which splits a transition into two or more concurrent transitions.

Caution

The outgoing transitions should not have guards. However ArgoUML will not enforce this.

A fork is represented on the diagram as a solid (black by default) horizontal bar.

Tip

This bar can be made vertical by selecting the fork, and dragging with button 1 one of its corners.
20.17. Join

Join is a pseudostate (see Section 20.11, “Pseudostate”) which joins two or more concurrent transitions into a single transition.

**Caution**

The incoming transitions should not have guards. However ArgoUML will not enforce this.

A join is represented on the diagram as a solid (black by default) horizontal bar.

**Tip**

This bar can be made vertical by selecting the join, and dragging with button 1 one of its corners.

20.18. Shallow History

Shallow History is a pseudostate (see Section 20.11, “Pseudostate”) that can remember the last state of its container that was active. The history pseudostate points to its default state with a transition arrow just like the initial pseudostate does. This transition points to the substate that will become active when there is no history. When the container composite state has been active before (i.e., when there is history), the substate that was active when the container state was exited, becomes active again.

When placed within a multi-level hierarchy of composite states, the shallow history only remembers the history for states that have the same container as the history pseudostate. It does not restore substates deeper in the hierarchy then the history pseudostate itself.

A shallow history is represented on the diagram as a circle containing the letter H.

20.19. Deep History

Deep History is a pseudostate (see Section 20.11, “Pseudostate”) that can remember the last state of its container that was active. The history pseudostate points to its default state with a transition arrow just like the initial pseudostate does. This transition points to the substate that will become active when there is no history. When the container composite state has been active before (i.e., when there is history), the substate that was active when the container state was exited, becomes active again.

When placed within a multi-level hierarchy of composite states, the deep history remembers the history for all states recursively which are contained in the history pseudostate container. It does restore any substates no matter how deep in the hierarchy.

A deep history is represented on the diagram as a circle containing the symbols H*.

20.20. Synch State

A synch state is for synchronizing concurrent regions of a state machine. It is used in conjunction with forks and joins to insure that one region leaves a particular state or states before another region can enter a particular state or states. The firing of outgoing transitions from a synch state can be limited by specifying a bound on the difference between the number of times outgoing and incoming transitions have fired. In the UML metamodel Synch is a child of StateVertex.
A synch state is shown as a small circle with the upper bound inside it. The bound is either a positive integer or a star (*) for unlimited. Synch states are drawn on the boundary between two regions when possible.

20.20.1. Synch State Details Tabs

The details tabs that are active for Synch states are as follows.

**ToDoItem**
Standard tab.

**Properties**

**Documentation**
Standard tab.

**Presentation**
Standard tab.

**Stereotype**
Standard tab, containing the stereotypes of the Synch state. In the UML metamodel, Synch State has no standard stereotypes defined.

**Tagged Values**
Standard tab. In the UML metamodel, Synch State has no standard tagged values defined.

20.20.2. Synch State Property Toolbar

**Go up**
Navigate up through the package structure.

**New Stereotype**
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected synch state, navigating immediately to the properties tab for that stereotype.

**Delete from Model**
This deletes the synch state from the model

**Warning**
This is a deletion from the model not just the diagram.

20.20.3. Property Fields For Synch State

**Name**
Text box. The name of the Synch state. By convention Synch state names start with a lower case letter and use bumpy caps to divide words within the name.
Note

ArgoUML does not enforce this naming convention.

Tip

Synch state names are not shown on the diagram and it is not usually necessary to give them a name.

Container

Text box. Shows the container of the Synch state. This is the state hierarchy.

Button 1 double click on the entry will navigate to the composite state that contains this state (or the top-level state that is the root of the state containment hierarchy).

Bound

Editable text box. Shows the Bound of the Synch state. Which is a positive integer or the value unlimited (represented by a "*") specifying the maximal count of the SynchState. The count is the difference between the number of times the incoming and outgoing transitions of the synch state are fired.

Incoming

Text area. Lists any incoming transitions for the final state.

Button 1 double-click navigates to the selected transition.

Outgoing Transitions

Text area. Lists any outgoing transitions for the final state.

Button 1 double-click navigates to the selected transition.
Chapter 21. Collaboration Diagram Artifact Reference

21.1. Introduction

This chapter describes each artifact that can be created within a collaboration diagram. Note that some sub-artifacts of artifacts on the diagram may not actually themselves appear on the diagram.

There is a close relationship between this material and the properties tab of the details pane (see Section 13.3, “Properties Tab”). That section covers Properties in general, in this chapter they are linked to specific artifacts.

**Caution**

Collaboration diagrams are not fully developed yet in ArgoUML. Many aspects are not fully implemented, or may not behave as expected. In particular there are some serious problems with layout of the collaboration roles and messages.

Figure 21.1, “Possible artifacts on a collaboration diagram.” shows a collaboration diagram with all possible artifacts displayed.

**Figure 21.1. Possible artifacts on a collaboration diagram.**

21.1.1. Limitations Concerning Collaboration Diagrams in ArgoUML

The collaboration diagram is still rather under-developed in ArgoUML. In particular there is no way to show instance collaborations (based on objects and links) rather than specification collaborations.

The biggest difficulties are with the messages. There are problems with the sequencing of the messages and their display on the diagram. The actions behind them are purely textual in implementation and there is no way to link them back to their associated operations or signals.

21.2. Classifier Role

A classifier role is a specialization of a classifier, used to show its behavior in a particular context. In the UML metamodel Classifier Role is a sub-class of Classifier. Within a collaboration diagram classifier roles may be used in one of two ways:

- To represent the classifier in a particular behavioral context (the specification level); or
- to specify a particular instance of the classifier (the instance level).

In this latter form, classifier roles are identical to the instances used in sequence diagrams (see Chapter 19, Sequence Diagram Artifact Reference) and a collaboration diagram shows the same information as the sequence diagram, but in a different presentation.
Caution

A collaboration diagram should not mix classifier roles used as the specifier level and the instance level.

A classifier role is represented on a sequence diagram in ArgoUML as a plain box labeled with the classifier role name (if any) and classifier, separated by a colon (:).

Caution

A classifier role should properly also show object name (if any) preceding the classifier role name and separated from it by a slash (/). This allows classifier roles in a specification level diagram to be distinguished from instances in an instance level diagram.

ArgoUML does show the slash, but there is no way to define the instances.

21.2.1. Classifier Role Details Tabs

The details tabs that are active for classifier roles are as follows.

ToDoItem
Standard tab.

Properties
See Section 21.2.2, “Classifier Role Property Toolbar” and Section 21.2.3, “Property Fields For Classifier Role” below.

Documentation
Standard tab.

Presentation
Standard tab.

Source
Standard tab, but with no contents.

Caution

A classifier role should not generate any code, so having this tab active is probably a mistake.

Tagged Values
Standard tab. In the UML metamodel, Classifier Role has the following standard tagged values defined.

• persistence (from the superclass, Classifier. Showing the permanence of the state information associated with the classifier role. Values transitory (state is destroyed when the classifier role is destroyed) and persistent (state is preserved when the classifier role is destroyed).

• semantics (from the superclass, Classifier). The value is a specification of the semantics of the classifier role.

• derived (from the superclass, ModelElement). Values true, meaning the classifier role is
redundant??it can be formally derived from other elements, or \textit{false} meaning it cannot.

\textbf{Note}

Derived classifier roles still have their value in analysis and design to introduce useful names or concepts, and in design to avoid re-computation.

\textbf{Note}

The UML \texttt{Element} metaclass from which all other artifacts are derived includes the tagged element \texttt{documentation} which is handled by the \texttt{documentation tab} under ArgoUML.

\section*{21.2.2. Classifier Role Property Toolbar}

\textbf{Go up}

Navigate up through the package structure.

\textbf{New reception}

This creates a new reception, navigating immediately to the properties tab for that reception.

\textbf{New Stereotype}

This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected classifier role, navigating immediately to the properties tab for that stereotype.

\textbf{Delete}

This deletes the classifier role from the model.

\textbf{Warning}

This is a deletion from the model \textit{not} just the diagram. To delete an classifier role from the diagram, but keep it within the model, use the main menu \texttt{Remove From Diagram} (or press the Delete key).

\section*{21.2.3. Property Fields For Classifier Role}

\textbf{Name}

Text box. The name of the classifier role. By convention classifier role names start with a lower case letter and use bumpy caps to divide words within the name.

\textbf{Note}

ArgoUML does not enforce this naming convention.

\textbf{Stereotype}

Drop down selector. Classifier Role is provided by default with the UML standard stereotypes for a classifier (\texttt{metaclass}, \texttt{powertype}, \texttt{process}, \texttt{thread} and \texttt{utility}).
Navigate Stereotype
donuts. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace
Text box. Records the namespace for the classifier role, which is always the containing Collaboration.

Button 1 double click on the entry will navigate to the collaboration.

Multiplicity
Editable drop down selector. The default value is *, which means that there are any number of instances of this classifier role that play a role in the collaboration. The drop down provides some different multiplicities. E.g. 1..1 would mean that only one instance plays a role in this collaboration.

ArgoUML does not restrict you to the predefined ranges for multiplicity. You can edit this field freely.

Base
List. The names of the classifiers of which this is a classifier role. Button 1 double click navigates to the classifier. Button 2 click gives a pop up menu with the following entries.

- Add. Allows adding or removing classifiers to the list. To this end, a dialog box pops up, as shown in the figure below.

Figure 21.2. The “add context” dialog box

- Remove. Allows removing classifiers to the list, without making use of the dialog box.

Generalizations
Text area. Lists any classifier that generalizes this classifier role.

Button 1 double click navigates to the generalization and opens its property tab.

Specializations
Text box. Lists any specialized classifier role (i.e. for which this classifier role is a generalization).

Button 1 double click navigates to the generalization and opens its property tab.

Association End Role
Text area. Lists the association-end roles that are linked to this classifier role.

Button 1 double click navigates to the selected entry.

Available Contents
Text area. Lists the subset of modelelements contained in the base classifier which is used in the collaboration.

Button 1 double click navigates to the modelelement and opens its property tab.

Available Features
Text box. Lists the subset of features of the base classifier which is used in the collaboration.

Button 1 double click navigates to the feature and opens its property tab.
21.3. Association Role

An association role is a specialization of an association, used to describe an associations behavior in a particular context. In the UML metamodel Association Role is a sub-class of Association.

An association role is represented on a collaboration diagram in ArgoUML as a line connecting the instances concerned. However on a sequence diagram the representation is modified to reflect the type of action associated with the stimulus carried on the link (see Section 19.3, “Stimulus”).

The association role is labeled with the association role name (if any).

An association role shows its name and the association name according the following syntax:

\[ / \text{AssociationRoleName} : \text{AssociationName} \]

in the same manner as a classifier role. The more generic syntax is:

\[ I / R : C \]

which stands for an Instance named I originating from the Classifier C playing the role R.

21.3.1. Association Role Details Tabs

The details tabs that are active for association roles are as follows.

**ToDoItem**
- Standard tab.

**Properties**
- See Section 21.3.2, “Association Role Property Toolbar” and Section 21.3.3, “Property Fields For Association Role” below.

**Documentation**
- Standard tab.

**Presentation**
- Standard tab. The values for the bounds of the association role are downlighted, since they are determined by what they connect.

**Source**
- Standard tab, but with no contents.

**Caution**

An association role should not generate any code, so having this tab active is probably a mistake.

**Tagged Values**
- Standard tab. In the UML metamodel, AssociationRole has the following standard tagged values defined.

- **persistence** (from the superclass, Association). Values transitory, indicating state is destroyed when an instance is destroyed or persistent, marking state is preserved when an instance is destroyed.

- **derived** (from the superclass, ModelElement). Values true, meaning the association is re-
dundant??it can be formally derived from other elements, or false meaning it cannot.

Note

Derived association roles still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.

Note

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

Checklist
Standard tab for an Association Role.

21.3.2. Association Role Property Toolbar

Go up
Navigate up through the package structure.

Delete
This deletes the association role from the model

Warning

This is a deletion from the model not just the diagram. To delete an association role from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

21.3.3. Property Fields For Association Role

Name
Text box. The name of the association role, which is shown on the diagram. By convention association role names start with a lower case letter and use bumpy caps to divide words within the name.

Note

ArgoUML does not enforce this naming convention.

Stereotype
Drop down selector. Association role is provided by default with the UML standard stereotype from the superclass Association: implicit.

Navigate Stereotype icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 18.4, “Stereotype”).

Namespace
Text box. Records the namespace for the association role. This is the package hierarchy.

Button 1 double click on the entry will navigate to the item shown.

**Base**
Drop down selector. Records the association that is the base for the association role.

The drop down selector shows all associations that exist between the classifiers that correspond with the connected classifier roles.

**Association End Roles**
Text area. Lists the ends of this association role. An association role can have any number of ends, but two is generally the only useful number (link objects can lead to a third end on instance level diagrams, but this is not supported by ArgoUML). For more on association end roles see Section 21.4, “Association End Role”.

The names are listed, unless the association end role has no name, then it is shown as (anon AssociationEndRole).

Button 1 double click on an association end role will navigate to that end.

**Messages**
Text area. Lists the messages that are associated with this association role.

Button 1 double click navigates to the selected entry

### 21.4. Association End Role

An association end role is a specialization of an association end, used to describe an association end's behavior in a particular context. In the UML metamodel AssociationEndRole is a sub-class of AssociationEnd.

Two or more association end roles are associated with each association role (see Section 21.3, “Association Role”), although for ArgoUML, the number of ends can only be two.

The association end role has no direct access on any diagram, although its stereotype, name and multiplicity is shown at the relevant end of the parent association role (see Figure 21.1, “Possible artifacts on a collaboration diagram.”), and some of its properties can be directly adjusted with button 2 click.

Where shared or composite aggregation is selected for one association end role, the opposite end is shown as a solid diamond (composite aggregation) or hollow diamond (shared aggregation).

**Note**

ArgoUML does not currently (V0.18) support showing qualifiers on the diagram, as described in the UML 1.4 standard.

**Caution**

An association end role should have the same, or “stricter” attribute values than its base association end. In particular its navigability should be no more general. There is as yet no critic in ArgoUML to offer advice on this rule.

### 21.4.1. Association End Role Details Tabs

The details tabs that are active for association end roles are as follows.
ToDoItem
  Standard tab.

Properties
  See Section 21.4.2, “Association End Role Property Toolbar” and Section 21.4.3, “Property Fields For Association End Role” below.

Documentation
  Standard tab.

Source
  Standard tab. There is no code generated for an association end role.

Tagged Values
  Standard tab. In the UML metamodel, AssociationEndRole has the following standard tagged values defined.

  • derived (from the superclass, ModelElement). Values true, meaning the association end role is redundant it can be formally derived from other elements, or false meaning it cannot.

  Tip
  Derived association end roles still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation. However the tag only makes sense for an association end role if it is also applied to the parent association role.

  Note
  The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML

21.4.2. Association End Role Property Toolbar

Go up
  Navigate up to the association role to which this end role belongs.

Go Opposite
  This navigates to the other end of the association role.

New Qualifier
  This creates a new Qualifier for the selected association-end role, navigating immediately to the properties tab for that qualifier.

  Warning
  Qualifiers are only partly supported in ArgoUML V0.18. Hence, activating this button creates a qualifier in the model, which is not shown on the diagram. Also, the properties panel for a qualifier equals that of a regular attribute.
New Stereotype

This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected association-end role, navigating immediately to the properties tab for that stereotype.

Delete

This deletes the selected association-end from the model.

Note

This button is downlighted for binary association roles, since an association needs at least two ends. Only for N-ary associations, this button is accessible, and deletes just one end from the association.

21.4.3. Property Fields For Association End Role

Name

Text box. The name of the association end role, which provides a role name for this end of the association role. This role name can be used for navigation, and in an implementation context, provides a name by which the source end of an association role can reference the target end.

Note

ArgoUML does not enforce any naming convention for association end roles.

Stereotype

Drop down selector. Association end role is provided by default with the UML standard stereotypes for AssociationEndRole (association, global, local, parameter, self).

Navigate Stereotype

icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Base

Text field that shows the name of the corresponding association end. Button 1 double click navigates to the association end.

AssociationRole

Text box. Records the parent association role for this association end role. Button 1 double click navigates to the association role.

Type

Drop down selector providing access to all standard UML types provided by ArgoUML and all new classes created within the current model.

This is the type of the entity attached to this end of the association role.

Multiplicity

Editable drop down text entry. Allows to alter the multiplicity of this association end role (with respect to the other end), i.e. how many instances of this end may be associated with an instance of the other end. The multiplicity is shown on the diagram at that end of the association role.

All remaining properties

See Section 18.12.3, “Property Fields For Association End”. Since these are completely equal to
the fields of an association end, they are not repeated here.

21.5. Message

A message is a communication between two instances of an association role on a specification level collaboration diagram. It describes an action which will generate the stimulus associated with the message. On a collaboration diagram a message is associated with an association role. In the UML metamodel Message is a sub-class of ModelElement.

The message is represented on a collaboration diagram in ArgoUML by its sequence number separated by a colon from the expression defining the associated action. It is accompanied by an arrow pointing in the direction of the communication, i.e. the direction of the AssociationRole. By convention the name of a message is not shown on the diagram. Instead the diagram displays the message sequence number, either as an integer or as a decimal number to show hierarchy.

Warning

The current release of ArgoUML does not retaining message positioning after reloading the project, i.e. as if the positions were not stored in the project file.

21.5.1. Message Details Tabs

The details tabs that are active for messages are as follows.

ToDoItem
Standard tab.

Properties
See Section 21.5.2, “Message Property Toolbar” and Section 21.5.3, “Property Fields For Message” below.

Documentation
Standard tab.

Presentation
Standard tab. The values for the bounds of the message define the bounding box of the message. The Line field defines the arrow color. Increasing the Shadow size has an esthetically questionable effect.

Caution

In the V0.18 release of ArgoUML changing the position of the message by editing the values of the Bounds field is possible, but will make only a temporary change to the position of the message, as described above.

Source
Standard tab, showing the message number and action expression separated by a colon (when UML 1.4 is selected in the drop-down).

Caution

A message probably should not generated any code of itself. That should be left to the action and possibly stimulus associated with it. In any case changes to this tab are ignorable.
Tagged Values

In the UML metamodel, Message has the following standard tagged values defined.

- **derived** (from the superclass, ModelElement). Values `true` meaning the message is redundant in that it can be formally derived from other elements, or `false` meaning it cannot.

**Note**

Derived messages still have their value in analysis and design to introduce useful names or concepts, and in design to avoid re-computation.

**Note**

The UML Element metaclass from which all other artifacts are derived includes the tagged element **documentation** which is handled by the **documentation tab** under ArgoUML.

### 21.5.2. Message Property Toolbar

**Go up**

Navigate up through the package structure.

**New Action**

This creates a new Action (see Section 20.3, “Action”) for the selected object, navigating immediately to the properties tab for that action.

**New Stereotype**

This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected message, navigating immediately to the properties tab for that stereotype.

**Delete**

This deletes the message from the model

**Warning**

This is a deletion from the model *not* just the diagram. To delete an message from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

### 21.5.3. Property Fields For Message

**Name**

Text box. The name of a message is usually its sequence number, either an integer, or a decimal (allowing alternative message hierarchies to be clearly described). ArgoUML will supply an integer
sequence number by default.

**Stereotype**
Drop down selector. Message has no stereotypes by default in the UML standard.

**Navigate Stereotype**
Icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Interaction**
Text box. Records the Interaction of which the message is a part.

Button 1 double click on the entry will navigate to the interaction.

**Sender**
Text box. Identifies the classifier role which sent this message.

Button 1 double click navigates to the sender classifier role.

**Receiver**
Text box. Identifies the classifier role which receives this message.

Button 1 double click navigates to the receiver classifier role.

**Activator**
Drop down selector. Identifies the message which invokes the behavior that causes the sending of this message.

Button 1 click allows selecting the message.

**Action**
Text box. Lists the action (see Section 20.3, “Action”) this message invokes to raise a stimulus.

Button 1 double click navigates to the selected action, button 2 gives a pop up menu with the following entry.

- **New.** Add a new action.

  This item is downlighted if an action already exists.

**Predecessors**
Text area. Identifies the messages, the completion of whose execution enables this message.

Button 1 double click navigates to the selected message, button 2 gives a pop up menu with one entry.

- **Add.** Opens a dialog box that allows to select any number of messages. See figure below.

  This entry is grayed out when no messages exist.

**Figure 21.3. The “add predecessors” dialog box**
Chapter 22. Activity Diagram Artifact

Reference

22.1. Introduction

This chapter describes each artifact that can be created within an Activity diagram. Note that some sub-artifacts of artifacts may not actually themselves appear on the diagram.

There is a close relationship between this material and the Properties Tab of the Details Pane (see Section 13.3, “Properties Tab”). That section covers Properties in general, in this chapter they are linked to specific artifacts.

Figure 22.1, “Possible artifacts on an activity diagram.” shows an Activity Diagram with all possible artifacts displayed.

Figure 22.1. Possible artifacts on an activity diagram.

22.1.1. Limitations Concerning Activity Diagrams in ArgoUML

Activity diagrams are not fully developed yet in ArgoUML. Some aspects are not fully implemented, or may not behave as expected. In particular lacking are call states, swim lanes, control icons (signals), sub-activities, synch states. Interactions with other classifiers are provided by an object-flow-state which is only partly implemented.

22.2. Action State

An action state represents execution of an atomic action, usually the invocation of an action. Within the UML metamodel, ActionState is a sub-class of SimpleState. It is a specialized simple state that only has an entry action, and with an implicit trigger as soon as that action is completed.

Caution

As a consequence any outgoing transitions from an action state should not have explicit triggers defined (ArgoUML will not currently check for this). They may have guards to provide a choice where there is more than one transition.

Note

Unlike an ordinary state, an internal transition, an exit action and a Do activity are not permitted for action states.

An action state is represented on an activity diagram in ArgoUML as a rectangle with rounded corners containing the name of the action state.

Caution
The UML standard specifies that the text shown in the action state on the activity diagram should contain the expression associated with the entry action - which is implemented as such since ArgoUML V0.18. In past versions of ArgoUML (0.16.1 and before), the diagram used to show the action state name. Loading a project created by one of the older versions, causes the project file to be converted to the correct format to conform to the UML standard. This process is designed to be transparent for the user, and the only drawback is, that the activity diagram in the project will not show correctly when reloaded in an old version of ArgoUML again.

### 22.2.1. Action State Details Tabs

The details tabs that are active for action states are as follows.

- **ToDoItem**
  - Standard tab.
- **Properties**
  - See Section 22.2.2, “Action State Property ToolBar” and Section 22.2.3, “Property fields for action state” below.
- **Documentation**
  - Standard tab.
- **Presentation**
  - Standard tab. The values for the bounds of the action state define the bounding box of the action state.
- **Stereotype**
  - Standard tab that shows the stereotypes of the action state. In the UML metamodel, there are no stereotypes defined by default for a action state.
- **Tagged Values**
  - Standard tab. In the UML metamodel, `ActionState` has no standard tagged values defined.

### 22.2.2. Action State Property ToolBar

- **Go up**
  - Navigate up through the containment structure. Action states are contained by the (otherwise invisible) top state.
- **New Stereotype**
  - This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected action state, navigating immediately to the properties tab for that stereotype.
- **Delete from Model**
  - This deletes the action state from the model

  **Warning**

  This is a deletion from the model *not* just the diagram. It is not possible to delete an action state from the diagram, since that concept does not fit the UML standard.
Hence ArgoUML does also not show the Add to Diagram pop-up menu for action states.

### 22.2.3. Property fields for action state

**Name**
Text box. The name of the action state. By convention action state names start with a lower case letter and use bumpy caps to divide words within the name.

**Note**
ArgoUML does not enforce this naming convention.

**Container**
Text box. The container of the action state. This shows the otherwise invisible composite state at the top of the containment hierarchy.

**Entry-Action**
Text box. Shows the name of the action to be invoked on entry to this action state. According the UML standard, an Action State is obliged to have an Entry-Action.

Button 1 double-click navigates to the shown entry, button 2 gives a pop up menu with two entries.

- **New.** Add a new Entry action of a certain kind. This menu has the following 7 submenus to select the kind of action: Call Action, Create Action, Destroy Action, Return Action, Send Action, Terminate Action, Uninterpreted Action.

- **Delete From Model.** Delete the Entry-Action.

**Deferrable events**
Text box. The deferrable events of the action state.

**Incoming**
Text area. Lists the transitions that enter this action state.

Button 1 double-click navigates to the selected entry.

**Outgoing**
Text area. Lists the transitions that leave this action state.

Button 1 double-click navigates to the selected entry.

### 22.3. Action

This artifact is described in the context of statechart diagrams (see Section 20.3, “Action”).

### 22.4. Transition

This artifact is described in the context of statechart diagrams (see Section 20.8, “Transition”).
Caution

Remember that action states do not have explicit triggers. The transition is implicitly triggered as soon as the entry event of the action state is complete. An explicit trigger should not therefore be set.

The current release of ArgoUML will not check that this constraint is met.

Note

Transitions to and from an ObjectFlowState are dashed, to distinguish object flow from control flow.

22.5. Guard

This artifact is described in the context of statechart diagrams (see Section 20.10, “Guard”).

22.6. Initial State

This artifact is described in the context of statechart diagrams (see Section 20.12, “Initial State”).

22.7. Final State

This artifact is described in the context of statechart diagrams (see Section 20.13, “Final State”).

22.8. Junction (Decision)

This artifact is described in the context of statechart diagrams (see Section 20.14, “Junction”).

22.9. Fork

This artifact is described in the context of statechart diagrams (see Section 20.16, “Fork”).

22.10. Join

This artifact is described in the context of statechart diagrams (see Section 20.17, “Join”).

22.11. ObjectFlowState

(To Be Written)
Chapter 23. Deployment Diagram Artifact Reference

23.1. Introduction

This chapter describes each artifact that can be created within a Deployment Diagram. Note that some sub-artifacts of artifacts on the diagram may not actually themselves appear on the diagram.

There is a close relationship between this material and the Properties Tab of the Details Pane (see Section 13.3, “Properties Tab”). That section covers Properties in general, in this chapter they are linked to specific artifacts.

Within ArgoUML, the deployment diagram is used for both component diagrams (i.e. without instances, showing static dependencies of components) and deployment diagrams (showing how instances of components are handled by instances of nodes at run-time).

Caution

Deployment diagrams are not fully developed yet in ArgoUML. Some aspects are not fully implemented or may not behave as expected. Notable omissions are the possibility to draw new interfaces and proper stereotyping of the various dependency relationships.

Figure 23.1, “Possible artifacts on a component diagram.” shows a component diagram with all possible artifacts displayed.

Figure 23.1. Possible artifacts on a component diagram.

Figure 23.2, “Possible artifacts on a deployment diagram.” shows a deployment diagram with all possible artifacts displayed.

Figure 23.2. Possible artifacts on a deployment diagram.

23.1.1. Limitations Concerning Deployment Diagrams in ArgoUML

The deployment diagram is generally well drawn, but there are only a subset of the relationships that should be shown available, which restricts the ability to show dynamic behavior of deployed code.

It is not possible to create new interfaces directly on this diagram; they can only be added if they are first created in the model (by drawing them on a class diagram).

It is an inconvenience that the alternative representation of an interface (as a small circle) is not supported.

23.2. Node
A node is a run-time physical object on which components may be deployed. In the UML metamodel it is a sub-class of **Classifier**.

A node is represented on a class diagram as a three dimensional box, labeled with its name.

### 23.2.1. Node Details Tabs

The details tabs that are active for nodes are as follows.

- **ToDoItem**
  - Standard tab.

- **Properties**
  - See Section 23.2.2, “Node Property Toolbar” and Section 23.2.3, “Property Fields For Node” below.

- **Documentation**
  - Standard tab.

- **Presentation**
  - Standard tab. The **Bounds**: field defines the bounding box for the node on the diagram.

  **Warning**

  Beware that in the 0.18 release of ArgoUML, the bounding box just refers to the front face of the cube. This means that the three dimensional top and side may be ignored, for example when determining the limits of a diagram for saving graphics.

- **Source**
  - Standard tab, but with no contents.

  **Caution**

  A node should not generate any code, so having this tab active is probably a mistake.

- **Tagged Values**
  - Standard tab. In the UML metamodel, **Node** has the following standard tagged values defined.

    - **persistence** (from the superclass, **Classifier**). Values **transitory**, indicating state is destroyed when an instance is destroyed or **persistent**, marking state is preserved when an instance is destroyed.

    - **semantics** (from the superclass, **Classifier**). The value is a specification of the semantics of the node.

    - **derived** (from the superclass, **ModelElement**). Values **true**, meaning the node is redundant (it can be formally derived from other elements), or **false** meaning it cannot.

  **Note**

  Derived nodes still have their value in analysis to introduce useful names or concepts, and in design to avoid re-computation.
Note

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

23.2.2. Node Property Toolbar

Go up
Navigate up through the package structure.

New reception
This creates a new reception, navigating immediately to the properties tab for that reception.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected node, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the node from the model

Warning
This is a deletion from the model not just the diagram. To delete a node from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

23.2.3. Property Fields For Node

Name
Text box. The name of the node. The name of a node has a leading capital letter, with words separated by “bumpy caps”.

Note
ArgoUML does not enforce this naming convention.

Stereotype
Drop down selector. Node is a type of classifier, and so it has the default stereotypes of a classifier as defined in the UML standard. ArgoUML provides the standard stereotypes for a classifier: metaclass, powertype, process, thread and utility.

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace
Drop down selector. Allows altering the namespace for the node. This is the package hierarchy.
Modifiers
Check box, with entries abstract, leaf and root.

- **abstract** is used to declare that this node cannot be instantiated, but must always be specialized. The name of an abstract node is displayed in italics on the diagram.

- **leaf** indicates that this node cannot be further specialized.

- **root** indicates the node can have no generalization.

Generalizations
Text area. Lists any node that generalizes this node.

Button double click navigates to the generalization and opens its property tab.

Specializations
Text box. Lists any specialized node (i.e. for which this node is a generalization.

Button double click navigates to the specialization and opens its property tab.

Residents
Text box. Lists any residents (see Section 23.4, “Component”) designed to be deployed on this type of node.

Button double click navigates to the selected entry.

---

### 23.3. Node Instance

A node instance is an instance of a node where component instances (see Section 23.5, “Component Instance”) may reside. In the UML metamodel `NodeInstance` is a sub-class of `Instance` and is specifically an instance that is derived from a node.

A node instance is represented on a deployment diagram in ArgoUML as a three dimensional box labeled with the node instance name (if any) and node type, separated by a colon (`:`).

**Tip**

It is the presence of the colon (`:`) and the underlining of the name and type that distinguishes a node instance from a node.

---

### 23.3.1. Node Instance Details Tabs

The details tabs that are active for node instances are as follows.

**ToDoItem**
Standard tab.

**Properties**
See Section 23.3.2, “Node Instance Property Toolbar” and Section 23.3.3, “Property Fields For Node Instance” below.

**Documentation**
Standard tab.
Presentation
Standard tab. The Bounds field defines the bounding box for the node instance on the diagram.

Warning
Beware that in the current release of ArgoUML, the bounding box just refers to the front face of the cube. This means that the three dimensional top and side may be ignored, for example when determining the limits of a diagram for saving graphics.

Source
Standard tab, containing just the name of the node instance.

Caution
A node instance should not generate any code, so having this tab active is probably a mistake.

Tagged Values
Standard tab.

Note
The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

Checklist
Standard tab for an Instance.

23.3.2. Node Instance Property Toolbar

Go up
Navigate up through the package structure.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected node instance, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the node instance from the model.

Warning
This is a deletion from the model not just the diagram. To delete an node instance from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

23.3.3. Property Fields For Node Instance
Name
Text box. The name of the node instance. By convention node instance names start with a lower case letter and use bumpy caps to divide words within the name.

Note
ArgoUML does not enforce this naming convention.

Stereotype
Drop down selector. Node instance has no stereotypes by default in the UML standard.

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace
Drop down selector. Records the namespace for the node instance. This is the package hierarchy.

Stimuli sent
(To Be Written).

Stimuli Received
(To Be Written).

Residents
Text box. Lists any residents (see Section 23.4, “Component”) designed to be deployed on this type of node.

Button 1 double click navigates to the selected entry.

Classifiers
Text field. A Node instance type can be selected here.

Caution
ArgoUML V0.18 lists many more items in the dropdown list then solely Nodes. Be-ware to select Nodes only.

23.4. Component

A component type represents a distributable piece of implementation of a system, including software code (source, binary, or executable) but also including business documents, etc., in a human system. Components may be used to show dependencies, such as compiler and run-time dependencies or information dependencies in a human organization. In the UML metamodel it is a sub-class of Classifier.

A component is represented on a class diagram as a box with two small rectangles protruding from its left side, labeled with its name.

23.4.1. Component Details Tabs

The details tabs that are active for components are as follows.
ToDoItem
Standard tab.

Properties
See Section 23.4.2, “Component Property Toolbar” and Section 23.4.3, “Property Fields For Component” below.

Documentation
Standard tab.

Presentation
Standard tab. The Bounds: field defines the bounding box for the component on the diagram.

Source
Standard tab, but with no contents.

Caution
A component should not generate any code, so having this tab active is probably a mistake.

Tagged Values
Standard tab.

Note
The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

23.4.2. Component Property Toolbar

Go up
Navigate up through the package structure.

New reception
This creates a new reception, navigating immediately to the properties tab for that reception.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected component, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the component from the model

Warning
This is a deletion from the model not just the diagram. To delete a component from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).
23.4.3. Property Fields For Component

Name
Text box. The name of the component. The name of a component has a leading capital letter, with words separated by “bumpy caps”.

Note
ArgoUML does not enforce this naming convention.

Stereotype
Drop down selector. Component is provided by default with the UML standard stereotypes document, executable, file, library and table. ArgoUML also provides the standard Classifier stereotypes, metaclass, powertype, process, thread and utility.

Navigate Stereotype
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

Namespace
Drop down selector. Records and allows altering the namespace for the component. This is the package hierarchy.

Modifiers
Check box, with entries abstract, leaf and root.

• Abstract is used to declare that this component cannot be instantiated, but must always be specialized.

• Leaf indicates that this component cannot be further specialized.

• Root indicates the node can have no generalization.

Generalizations
Text box. Lists any component that generalizes this component.

Specializations
Text area. Lists any derived components, i.e those for which this component is a generalization.

Client Dependencies
Text area. Lists outgoing dependencies. Button 1 double click navigates to the dependency.

Supplier Dependencies
Text area. Lists incoming dependencies. Button 1 double click navigates to the dependency.

Residents
Text box. Lists any residents (see Section 23.4, “Component”) designed to be deployed on this type of node.

Button 1 double click navigates to the selected entry.

23.5. Component Instance

A component instance is an instance of a component (see Section 23.4, “Component”) which may reside on a node instance (see Section 23.3, “Node Instance”). In the UML metamodel ComponentIn-
stance is a sub-class of Instance and is specifically an instance that is derived from a component.

A component is represented on a class diagram as a box with two small rectangles protruding from its left side, labeled with its name.

A component instance is represented on a sequence diagram in ArgoUML as a box with two small rectangles protruding from its left side labeled with the component instance name (if any) and component type, separated by a colon ( :).

**Tip**

It is the presence of the colon (:) and the underlining of the name and type that distinguishes a component instance from a component.

### 23.5.1. Component Instance Details Tabs

The details tabs that are active for component instances are as follows.

**ToDoItem**

Standard tab.

**Properties**

See Section 23.5.2, “Component Instance Property Toolbar” and Section 23.5.3, “Property Fields For Component Instance” below.

**Documentation**

Standard tab.

**Presentation**

Standard tab. The **Bounds**: field defines the bounding box for the component on the diagram.

**Source**

Standard tab, containing just the name of the component instance.

**Caution**

A component instance should not generate any code, so having this tab active is probably a mistake.

**Tagged Values**

Standard tab.

**Note**

The UML Element metaclass from which all other artifacts are derived includes the tagged element documentation which is handled by the documentation tab under ArgoUML.

**Checklist**

Standard tab for an Instance.

### 23.5.2. Component Instance Property Toolbar
Go up
Navigate up through the package structure.

New Stereotype
This creates a new Stereotype (see Section 16.5, “Stereotype”) for the selected component instance, navigating immediately to the properties tab for that stereotype.

Delete
This deletes the component instance from the model

**Warning**
This is a deletion from the model *not* just the diagram. To delete a component instance from the diagram, but keep it within the model, use the main menu Remove From Diagram (or press the Delete key).

### 23.5.3. Property Fields For Component Instance

**Name**
Text box. The name of the component instance. By convention component instance names start with a lower case letter and use bumpy caps to divide words within the name.

**Note**
ArgoUML does not enforce this naming convention.

**Stereotype**
Drop down selector. Component instance has no stereotypes by default in the UML standard.

**Navigate Stereotype**
icon. If a stereotype has been selected, this will navigate to the stereotype property panel (see Section 16.5, “Stereotype”).

**Namespace**
Drop down selector. Records and allows to change the namespace for the component instance. This is the package hierarchy.

**Stimuli sent**
(To Be Written).

**Stimuli Received**
(To Be Written).

**Residents**
Text box. Lists any residents (see Section 23.4, “Component”) designed to be deployed on this component.

Button 1 double click navigates to the selected entry.

**Classifiers**
Drop down selector. A Component instance type can be selected here.
Caution
ArgoUML V0.18 lists many more items in the dropdown list than solely Components. Beware to select Components only.

23.6. Dependency
A key part of any component or deployment diagram is to show dependencies. For details see Section 18.13, “Dependency”.

Caution
UML relies on stereotyping of dependencies on component and deployment diagrams to characterize the types of relationship. In the current release of ArgoUML there are limitations in the implementation of dependencies which limit this functionality.

23.7. Class
A component diagram may show the key internal structure of components, including classes within the component. For details see Section 18.5, “Class”.

Caution
Classes can only be added to a component diagram if they already exist in the model (by selecting them in the explorer and executing the “Add to diagram” button 2 command). There is no way to create a new class on a component diagram.

23.8. Interface
A component or deployment diagram may show components or component instances which implement interfaces. For details see Section 18.15, “Interface”.

Caution
The V0.18 release of ArgoUML uses the same representation of an interface as a class diagram. The UML standard suggests that an interface on a component or deployment diagram should just be shown as a small open circle, connected to the component which realizes that interface.

Warning
There is no way to show the linking of an interface to a component or component instance in the V0.18 release of ArgoUML.

23.9. Association
Components may be associated to each other. For details about associations, see Section 18.11,
“Association”.

Where classes or interfaces are shown within components on component diagrams, they may be shown linked by associations.

23.10. Object

Just as components may show the classifiers that make up their internal structure, component instances on deployment diagrams may show the classifier instances that make up their internal structure. In practice the only instance that is of use is an object (an instance of a class). For details see Section 19.2, “Object”.

23.11. Link

Where objects (Node Instances or Class Instances) are shown within component instances on deployment diagrams, their inter-relationships may be shown as links (instances of an association). See Section 19.9, “Link” for details.
Chapter 24. Built In DataTypes, Classes, Interfaces and Stereotypes

24.1. Introduction

This chapter describes the datatypes, classes, interfaces and stereotypes, which by default, are built in to ArgoUML.

Datatypes, classes and interfaces are generally available for use anywhere a class may be selected in the properties tab. The most common use is for return type and parameter types in method signatures.

24.1.1. Package Structure

ArgoUML datatypes, classes and interfaces are effectively organized as a hierarchy beneath the overall model itself. They are grouped in four packages, lang, math, net and util, themselves subpackages of java, which is a subpackage of the model itself. Figure 24.1, “Hierarchy of datatypes, classes and interfaces within ArgoUML” shows this structure.

Figure 24.1. Hierarchy of datatypes, classes and interfaces within ArgoUML

24.1.2. Exposure in the model

You will not find build-in DataTypes, Classes, and Interfaces exposed within the model by default (i.e. they are not present in the explorer). However, once you select one of the built-in DataTypes, Classes, or Interfaces (in the "Type" combo-box on the property sheet of a parameter of an operation of a class), then it becomes visible: you will find that the DataType, Class, or Interface has appeared in the model, in its correct package structure for the latter 2.

24.2. Built In Datatypes

These are the built in atomic types. You can change them if you wish. However this is not good practice.

All these can be found in the java.lang subpackage of the main model.

Caution

You should be aware that these are Java datatypes. They are not mandated by the UML standard.

These are the standard datatypes. For their definition refer to the Java standard.

• boolean
• byte
• char

285
24.3. Built In Classes

These are the common classes, corresponding to classes defined within the standard Java environment. It is up to you if you wish to change them.

These are found in all four subpackages of the java subpackage.

For a definition of these classes see the Java language and library definitions.

24.3.1. Built In Classes From java.lang

These are the classes within the java.lang package.

- Boolean
- Byte
- Char
- Double
- Float
- Integer
- Long
- Object
- Short
- String

24.3.2. Built In Classes From java.math

These are the classes within the java.math package.
24.3.3. Built In Classes From `java.net`

These are the classes within the `java.net` package.

- URL

24.3.4. Built In Classes From `java.util`

These are the classes within the `java.util` package.

- Vector
- Date
- Time

24.4. Built In Interfaces

These are some useful interfaces, corresponding to classes defined within the standard Java environment. Interfaces have many of the properties of classes (like all types) and you can change them if you wish.

All these can be found in the `java.util` subpackage of the main model.

These are the interfaces defined within the `java.util` package. For their definition consult the Java language and library references.

- Collection
- Iterator
- List
- Set
- Sorted Set

24.5. Built In Stereotypes

UML 1.4 defines a large number of stereotypes of which most are supported by ArgoUML.

**Caution**

Not all stereotypes defined by UML 1.4 appear in ArgoUML V0.20 due to the fact that they were not yet updated from previous versions of ArgoUML that only supported UML
1.3. Also, there are limitations in the current implementation of some base elements. The table below lists all stereotypes defined in UML 1.4 and if they are supported in ArgoUML or not.

**Caution**

The UML 1.4 standard also specifies many stereotypes in the chapters “Example Profiles”: one for “Software Development” and one for “Business Modeling”. Due to the specialized nature of these profiles, implementation in ArgoUML is postponed until a yet undetermined moment.

### Table 24.1. Stereotypes defined in UML 1.4 and ArgoUML

Glossary

A

Activity Diagram
A UML diagram capturing the dynamic behavior of a system or subsystem. See Section 6.10, “Activity Diagrams (To be written)” for more information.

Action
Behavior associated with States or Transitions in State Diagram. These actions are invocations of Methods and appear on Sequence and Collaboration Diagrams.

Actor
A representation of an agent (animate or inanimate) on a Use Case Diagram external to the system being designed.

Analysis
Analysis is the process of taking the “customer” requirements and re-casting them in the language of, and from the perspective of, a putative solution.

Association Class
A class that characterizes the association between two other classes.

Association
A relationship between two classes in a Class Diagram or between Use Cases or Use Cases and Actors in a Use Case Diagram.

Attribute (of a Class or Object)
An attribute of a class or object is a specification of a data element encapsulated by that object.

C

CASE
Computer Aided Software Engineering.

Class
The encapsulation of the data associated with an artifact (its attributes) and the actions associated with the artifact (its methods).

A class specifies the characteristics of an artifact. An object represents an instance of the artifact.

Classes and objects in UML are represented on Activity Diagrams, Class Diagrams, Collaboration Diagrams and Sequence Diagrams.

Class Diagram
A UML Diagram showing the structural relationship between classes. See Section 5.2, “Class Diagrams (To be written)” for more information.
Collaboration
The process whereby several objects cooperate to provide some higher level behavior that is greater than the sum of the behaviors of the objects.

Collaboration Diagram
A UML Diagram showing the dynamic behavior as messages are passed between objects. Equivalent to a Sequence Diagram. Which representation is appropriate depends on the problem under consideration.

Collaborator
An object that participates in a Collaboration.

Comprehension and Problem Solving
A design visualization theory within cognitive psychology. The theory notes that designers must bridge a gap between their mental model of the problem or situation and the formal model of a solution or system.

This theory suggests that programmers will benefit from:

1. Multiple representations such as program syntactic decomposition, state transitions, control flow, and data flow. These allow the programmer to better identify elements and relationships in the problem and solution and thus more readily create a mapping between their situation models and working system models.

2. Familiar aspects of a situation model, which improve designers' abilities to formulate solutions.

Concept Class Diagram
A Class Diagram constructed during the Analysis Phase to show the main structural components of the problem identified in the Requirements Phase. See Chapter 5, Analysis for more information.

Critic
A process within ArgoUML that provides suggestions as to how the design might be improved. Suggestions are based on principles within three theories of cognitive psychology, reflection-in action, opportunistic design and comprehension and problem solving.

Extend Relationship
A relationship between two Use Cases, where the extended Use Case describes a special variant of the extending Use Case.

Generalization Relationship
A relationship between one generalizing Use Cases and one or more generalized Use Cases, where the generalized Use Cases are partic-
ular examples of the generalizing Use Case.

GUI

Graphical User Interface.

Hierarchical Statechart Diagram

A Statechart Diagram that contains subsidiary statechart diagrams within individual States.

Include Relationship

A relationship between two Use Cases, where the included Use Case describes part of the functionality of the including Use Case.

Iterative Design Process

A design process where each all phases (requirements, analysis, design, build, test) are tackled partially in a series of iterations. See Section 3.2.1, “Tipos de Procesos” for more information.

Java

A fully object oriented programming language introduced by Sun Microsystems. More strongly typed than C++, it compiles to an interpreted code, the Java Virtual Machine (JVM). The JVM means that Java code should run on any machine that has implemented the JVM.

The most significant component of Java was integration of the JVM into web browsers, allowing code (Applets) to be download and run over the web.

ArgoUML is written in Java.

Moore Machine

A Statechart Diagram where actions are associated with Transitions.

Mealy Machine

A Statechart Diagram where actions are associated with States.

Method (of a Class or Object)

A method of a class or object is a specification of behavior encapsulated by that object.
**Object**

An instance of a *Class*.

Classes and objects in UML are represented on *Activity Diagrams, Class Diagrams, Collaboration Diagrams* and *Sequence Diagrams*.

**OCL**

Object Constraint Language. A language for describing constraints within UML.

**OMG**

The Object Management Group. An international industry standardization body. Best known for CORBA and UML.

**OOA&D**

Object Oriented Analysis and Design. An approach to software problem analysis and design based on objects, which encapsulate both data and code. See See Section 1.1.1, “Analisis Orientado a Objeto y Diseño” or any standard textbook on Software Engineering.

UML is a notation to support OOA&D.

**Opportunistic Design**

A theory within cognitive psychology suggesting that although designers plan and describe their work in an ordered, hierarchical fashion, in actuality, they choose successive tasks based on the criteria of cognitive cost. Simply stated, designers do not follow even their own plans in order, but choose steps that are mentally least expensive among alternatives.

**Pane**

A sub-window within the main window of the ArgoUML user interface.

**Realization Use Case**

A *Use Case* where the *Use Case Diagram* and *Use Case Specification* are in the language of the solution domain, rather than the problem domain.

**Reflection-in-Action**

A theory within cognitive psychology which observes that designers of complex systems do not conceive a design fully-formed. Instead, they must construct a partial design, evaluate, reflect on, and revise it, until they are ready to extend it further. As developers work hands-on with the design, their mental model of the problem situation improves, hence improving their design.
### Requirement Capturing

Requirement capturing is the process of identifying what the “customer” wants from the proposed system. See Chapter 4, *Capitara de Requerimientos* for a fuller description.

### Responsibility

Some behavior for which an object is held accountable. A responsibility denotes the obligation of an object to provide a certain behavior.

### Scenario

A specific sequence of actions that illustrates behavior.

### Sequence Diagram

A UML Diagram showing the dynamic behavior as messages are passed between objects. Equivalent to a *Collaboration Diagram*. Which representation is appropriate depends on the problem under consideration. See Section 5.4, “Sequence Diagrams (To be written)” for more information.

### SGML

### Simula 67

A procedural programming language intended for simulation. Noted for its introduction of *objects* and *coroutines*.

### State

Within a *Statechart Diagram* a one of the possible configurations of the machine.

### Statechart Diagram

A UML Diagram showing the dynamic behavior of an active *Object*. See Section 5.6, “Statechart Diagrams (To be written)” for more information.

### Stereotypes and Stereotyping

Any artifact within UML can be given a *stereotype* to indicate its association with a particular role in the design. A stereotype spqr is generally indicated with the notation <<spqr>>.

A stereotype defines a Namespace within the design. Examples of stereotypes are <<business>> and <<realization>> for Use Cases, used to distinguish between Use Cases at the requirements phase defined in terms of the problem domain, and Use Cases at the analysis phase defined in terms of the solution domain.

### Supplementary Requirement Specification

The document capturing non-functional requirements that cannot be associated with Use Cases.

### SVG

Scalable Vector Graphics format. A standard representation of graphics diagrams that use vectors. ArgoUML can export diagrams in SVG.

**Waterfall Design Process**

A design process where each phase (requirements, analysis, design, build, test) is completed before the next starts. See Section 3.2.1, “Tipos de Procesos” for more information.

**XMI**

XML Model Interchange format. A format for file storage of UML models. Currently incomplete, since it does not carry all graphical layout information, so must be supplemented by files carrying that information.

**XML**

eXtensible Markup Language. A simplified derivative of SGML defined by W3C
Appendix A. Supplementary Material for the Case Study

A.1. Introduction

The case study requires various material (mostly documents) that live alongside the design diagram.

A.2. Requirements Documents (To be written)

A.2.1. Vision Document (To be written)

A.2.2. Use Case Specifications (To be written)

A.2.2.1. UC Specification 1 (To be written)

A.2.3. Supplementary Requirements Specification (To be written)
Appendix B. UML resources

B.1. The UML specs (To be written)

C.1. Other Open Source Projects (To be written)

To be written...

C.2. Commercial Tools (To be written)

To be written...
Appendix D. The C++ Module

The ArgoUML C++ Module (C++ Mod.) provides C++ code generation functionalities and C++ notation within ArgoUML. It works the same way as the other languages' modules.

D.1. Modeling for C++

The C++ programming language has constructs that aren't contained by default in UML. Examples are pointers, global functions and variables, references and operator overloading. To enable us to apply these constructs in our models and be capable of taking advantage of it for code generation and C++ notation in UML diagrams, the C++ module uses conventions in the use of the extension features of UML, tagged values and stereotypes.

Since UML and C++ are object oriented, there is an obvious correspondence between the UML model elements and C++ structural constructs, e.g, the UML Class is related to the C++ class. These obvious relations will not be described here, since it is assumed that an ArgoUML user that wants to model for C++ has basic knowledge of both C++ and UML.

Tagged values are one of the main means by which we can define code generation behavior. They have a name ?? the tag ??? and a value, and are applied to model elements.

The tagged values in use for the C++ module have two categories:

- free format values ??? any String is valid, except the empty String

- formated values ??? the value must obey some restrictions, e.g., be one of true or false (abbreviated to true || false)

For Boolean tagged values, only the values "true" or "false" are applicable. If a Boolean tagged value does not exist or is invalid for one model element, a default value is assumed by the code generator. In the bellow documentation the default value is marked.

Free format tagged values are only significant if present and if the value isn't an empty String. When the value must follow some sort of format, that is explicitly stated. In this case, there is the chance that the value is invalid. If the value is invalid, no assumptions are made; the generator will trace the problem and ignore the tagged value.

D.1.1. Class tagged values

constructor

true ??? generates a default constructor for the class.

false (default) ??? no default constructor is generated, unless it is explicitly modeled with the ???create?? stereotype.

header_incl

Name of the file to include in the header.

Note

If we desire to have multiple headers included this way, just use multiple tagged values with header_incl as the tag.
Other tagged values used for C++ modeling may also be used this way. This note won’t be repeated in those cases.

**source_incl**
Name of the file to include in the source (.cpp file).

**typedef_public**
<source type> <type name> creates typedef line in the public area of the class with typedef <source type> <type name>.

**typedef_protected**
Same as typedef_public, but in protected area.

**typedef_private**
Same as typedef_public, but in the private area.

**typedef_global_header**
Same as typedef_public, but, in the global area of the header.

**typedef_global_source**
Same as typedef_global_source, but, in the source file.

**TemplatePath**
Directory will search in the specified directory for the template files "header_template" and "cpp_template" which are placed in top of the corresponding file. The following tags in the template file are replaced by model values: |FILENAME|, |DATE|, |YEAR|, |AUTHOR|, |EMAIL|. If no such tag is specified, the templates are searched in the subdirectory of the root directory for the code generation.

**email**
name@domain.country replaces the tag |EMAIL| of the template file.

**author**
name replaces the tag |AUTHOR| of the template file.

**Note**
You may simply use the Author property in the documentation property panel.

**D.1.2. Attribute tagged values**

UML Attributes are mapped to class member variables.

**pointer**
true the type of the member variable will be a pointer to the attribute type.

For example, if you have the UML Attribute: name: std::string, with the pointer tagged value set to true, the generated member variable would be: std::string* name;

false (default) no pointer modifier is applied.

**reference**
true the type of the member variable will be a reference to the attribute type.
false (default) ??? no reference modifier is applied.

usage
header ??? will lead for class types to a pre-declaration in the header, and the include of the remote class header in the header of the generated class.

MultiplicityType
list || slist || vector || map || stack || stringmap ??? will define a multiplicity as the corresponding STL container, if the Multiplicity range of the attribute is variable (for fixed size ranges this setting is ignored).

set
private || protected || public ??? creates a simple function to set the attribute by a function (call by reference is used for class-types, else call by value); place the function in the given visibility area.

get
private || protected || public ??? as for set.

D.1.3. Parameters

D.1.3.1. Variable passing semantics

If a Parameter for an Operation is marked as out or inout the variable will be passed by reference (default) or pointer (needs tagged value pointer ??? see above), otherwise by value.

Return values in UML are simply Parameters marked as return, therefore everything here applies to them, except where explicitly noted.

Warning

Note that UML allows multiple return values. This is possible to support in C++ as out parameters, but, currently the generator doesn't support it.

This problem is being handled in issue #3553 ??? handle multiple return parameters [https://argouml.tigris.org/issues/show_bug.cgi?id=3553].

D.1.3.2. Parameter tagged values

pointer
true || false (default) ??? same as for Attributes.

reference
ditto

D.1.4. Preserved sections

With each code generation, special comments around the member function definitions will be generated like this:

function Testclass::Testclass()
// section -64--88-0-40-76f2e8:ec37965ae0:-7fff begin
All code you put within the "begin" and "end" lines will be preserved when you generate the code again. Please do not change anything within these lines because the sections are recognized by this comment syntax. As the curly braces are placed within the preserved area, attribute initializers are preserved on constructors.

This also works if you change Method Names after the generation.

```cpp
void newOperation(std::string test = "fddsaffa")
// section 603522:ec4c7ff768:-7ffc begin
{
}
// section 603522:ec4c7ff768:-7ffc end
```

If you delete an Operation in the model. The next time the class is generated, the lost code ??? i.e., the whole member function definition ??? will be added as comment to the end of the file.
Appendix E. Limits and Shortcomings

As all products, ArgoUML has some limits. Those important to the user are listed in this section.

E.1. Diagram Canvas Size

Due to the underlying diagram editing software, the canvas size for diagrams is limited to 6000 units in height and width.

E.2. Missing functions
Appendix F. Open Publication License

F.1. Requirements On Both Unmodified And Modified Versions

The Open Publication works may be reproduced and distributed in whole or in part, in any medium physical or electronic, provided that the terms of this license are adhered to, and that this license or an incorporation of it by reference (with any options elected by the author(s) and/or publisher) is displayed in the reproduction.

Proper form for an incorporation by reference is as follows:

Copyright (c) <year> by <author's name or designee>. This material may be distributed only subject to the terms and conditions set forth in the Open Publication License, vX.Y or later (the latest version is presently available at http://www.opencontent.org/openpub/ [http://www.opencontent.org/openpub/]).

The reference must be immediately followed with any options elected by the author(s) and/or publisher of the document (see section VI).

Commercial redistribution of Open Publication-licensed material is permitted.

Any publication in standard (paper) book form shall require the citation of the original publisher and author. The publisher and author's names shall appear on all outer surfaces of the book. On all outer surfaces of the book the original publisher's name shall be as large as the title of the work and cited as possessive with respect to the title.

F.2. Copyright

The copyright to each Open Publication is owned by its author(s) or designee.

F.3. Scope Of License

The following license terms apply to all Open Publication works, unless otherwise explicitly stated in the document.

Mere aggregation of Open Publication works or a portion of an Open Publication work with other works or programs on the same media shall not cause this license to apply to those other works. The aggregate work shall contain a notice specifying the inclusion of the Open Publication material and appropriate copyright notice.

SEVERABILITY. If any part of this license is found to be unenforceable in any jurisdiction, the remaining portions of the license remain in force.

NO WARRANTY. Open Publication works are licensed and provided “as is” without warranty of any kind, express or implied, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose or a warranty of non-infringement.

F.4. Requirements On Modified Works

All modified versions of documents covered by this license, including translations, anthologies, compil-
ations and partial documents, must meet the following requirements:

1. The modified version must be labeled as such.
2. The person making the modifications must be identified and the modifications dated.
3. Acknowledgement of the original author and publisher if applicable must be retained according to normal academic citation practices.
4. The location of the original unmodified document must be identified.
5. The original author's (or authors') name(s) may not be used to assert or imply endorsement of the resulting document without the original author's (or authors') permission.

F.5. Good-Practice Recommendations

In addition to the requirements of this license, it is requested from and strongly recommended of redistributors that:

1. If you are distributing Open Publication works on hardcopy or CD-ROM, you provide email notification to the authors of your intent to redistribute at least thirty days before your manuscript or media freeze, to give the authors time to provide updated documents. This notification should describe modifications, if any, made to the document.
2. All substantive modifications (including deletions) be either clearly marked up in the document or else described in an attachment to the document.
3. Finally, while it is not mandatory under this license, it is considered good form to offer a free copy of any hardcopy and CD-ROM expression of an Open Publication-licensed work to its author(s).

F.6. License Options

The author(s) and/or publisher of an Open Publication-licensed document may elect certain options by appending language to the reference to or copy of the license. These options are considered part of the license instance and must be included with the license (or its incorporation by reference) in derived works.

A. To prohibit distribution of substantively modified versions without the explicit permission of the author(s). “Substantive modification” is defined as a change to the semantic content of the document, and excludes mere changes in format or typographical corrections.

To accomplish this, add the phrase “Distribution of substantively modified versions of this document is prohibited without the explicit permission of the copyright holder.” to the license reference or copy.

B. To prohibit any publication of this work or derivative works in whole or in part in standard (paper) book form for commercial purposes is prohibited unless prior permission is obtained from the copyright holder.

To accomplish this, add the phrase “Distribution of the work or derivative of the work in any standard (paper) book form is prohibited unless prior permission is obtained from the copyright holder.” to the license reference or copy.
F.7. Open Publication Policy Appendix:

(This is not considered part of the license.)

Open Publication works are available in source format via the Open Publication home page at http://works.opencontent.org/ [http://works.opencontent.org/].

Open Publication authors who want to include their own license on Open Publication works may do so, as long as their terms are not more restrictive than the Open Publication license.

If you have questions about the Open Publication License, please contact David Wiley [mailto:dw2@opencontent.org], and/or the Open Publication Authors’ List at opal@opencontent.org [mailto:opal@opencontent.org], via email.

To subscribe to the Open Publication Authors' List: Send E-mail to opal-request@opencontent.org with the word “subscribe” in the body.

To post to the Open Publication Authors’ List: Send E-mail to opal@opencontent.org or simply reply to a previous post.

To unsubscribe from the Open Publication Authors’ List: Send E-mail to opal-request@opencontent.org with the word “unsubscribe” in the body.
Appendix G. The CRC Card Methodology

A CRC card is ostensibly an index card that is used to represent classes, their responsibilities, and the interactions between them. The term CRC card is also used to refer to a methodology for object oriented modeling based on their use.

Kent Beck and Ward Cunningham introduced CRC cards in a paper "A Laboratory for Teaching Object-Oriented Thinking" that was presented at the OOPSLA (Object-Oriented Programming, Systems, Languages & Applications) conference in 1989. A tutorial on the subject can be found at http://www.csc.calpoly.edu/~dbutler/tutorials/winter96/crc_b/. The CRC card methodology was originally designed as a teaching tool but has proved useful as a modeling tool as well.

The three parts of the CRC acronym were felt by the authors of the paper to represent the essential dimensions of object oriented modeling. The term Responsibilities refers to the contract that the class under discussion offers to the rest of the world (Interface and Contract are similar concepts). Responsibilities model the things that a class can do. Services, Methods, or Operations will result from these. The term Collaborators refers to the classes whose services the class under discussion will use. Kent Beck tried unsuccessfully to use their term Helpers instead of Collaborators to indicate classes that were supporting the class under discussion. It is widely believed that the terminology was chosen because CRC are the initials of Ward Cunningham's son.

Why use CRC cards?

• They are portable. No computers are required so they can be used anywhere. Even away from the office.

• They allow the participants to experience first hand how the system will work. No computer tool can replace the interaction that happens by physically picking up the cards and playing the role of that object.

• They are a useful tool for teaching people the object-oriented paradigm.

• They can be used as a methodology themselves or as a front end to a more formal methodology such as Booch, Wirfs-Brock, Jacobson, etc. Although CRC cards were created for teaching, they have proven useful for much more.

• They have become an accepted method for analysis and design. The biggest contributing factor to their success is the fact that they provide an informal and non threatening environment that is productive to working and learning.

G.1. The Card

The exact format of the card can be customized to the preferences of the group, but the minimal required information is the name of the class, it's subclasses and superclasses, it's responsibilities and the collaborators for each of those responsibilities. The back of the card can be used for a description of the class. During the design phase attributes of the class can be recorded on the back as well. One way to think of the card is that the front contains the public information, and the back contains the encapsulated, implementation details. As a class is defined a card is made for that class with its name entered. When a class is assigned to an individual that has only a class name on it, the individual (or the group) selects an initial set of responsibilities for the class. This initial set should be whatever (if anything) is immediately obvious.
The CRC Card Methodology

G.2. The Group

Whether they are implicitly or explicitly defined the requirements for the system need to be familiar to the people participating in the group.

The ideal group size for a CRC card session is five or six people. This size generally allows everyone to productively participate. In groups of larger size productivity is cut by more disagreements and the amount of participation by each is lower. If there are more than six people, one solution is to have the extra people be present strictly as observers.

The group five or six people in the core group should be composed of developers, domain experts, and an object-oriented technology facilitator.

G.3. The Session

Before starting a session a part of the problem needs to be selected for the session to focus on. Essentially, this means picking the set of classes that are to be used.

Pick the scenarios that are to be walked through that use the classes picked above. Start with scenarios that are part of the systems normal operation first, and then exceptional scenarios, like error recover, later.

Assign each class to a member of the group. Each person should be responsible for at least one class. They are the owner of that class for the session. Each person records the name of their class on a card. One class per card.

Walk-throughs are the heart of the CRC card session. To walk through a scenario address each action in it one at a time. First decide which class is responsible for this function. The owner of the class then picks up his card and holds it up in the air. When a card is up in the air it is an object and can do things. The owner announces that he needs to fulfill his responsibility. The responsibility is refined into smaller tasks if possible. These smaller tasks can be fulfilled by the object is appropriate or they can be fulfilled by interacting with other objects (collaborators). If no other appropriate class exists, you may need to make one and assign it to someone. This is the fundamental procedure of the scenario execution.

G.4. The Process

CRC Cards are used in the Analysis and Design phases. The process for these phases differ primarily in how the classes and scenarios are chosen.

In the Analysis phase the classes and scenarios are in the problem space and generally derive from the requirements. In the Design phase solution space classes and scenarios are added. Additionally in the Analysis phase the very first session starts with no classes or scenarios to select from so a special session creates them.
